### THE CORRECTION OF NASAL DEFORMITIES BY SUBCUTANEOUS OPERATIONS.

A FURTHER CONTRIBUTION.*

By JOHN O. ROE, M.D.
ROCHESTER, N. Y.

In 1887 I had the honor of first presenting before this society an article on this subject, entitled "The Deformity Termed Pug Nose and Its Correction by a Simple Operation." Since that time, on different occasions, I have presented papers describing various operations, by which the different deformities of the nose can be corrected by subcutaneous methods without wounding or disfiguring the skin.

The difficulties attending these operations and the experience required in their performance have doubtless deterred many from undertaking them, while the injection of paraffin, a method recently introduced by Gersuny, of Vienna, for the elevation of sunken portions of the nose, has, on account of its apparent simplicity, become quite popular, notwithstanding the fact that it is not devoid of local ill effects, or even disastrous general results, as shown by the reports of such cases.

While these subcutaneous operations for the correction of nasal deformities do not demand the bold and often hazardous procedure of the general surgeon in the performance of the major operations, they yet require most accurate work and a careful attention to details.

The success of these operations also depends upon an accurate knowledge of the plastic art, and also upon the ability of the surgeon to reconstruct the organ so as to preserve its own proper proportions and to retain its harmonious relations to the neighboring parts.

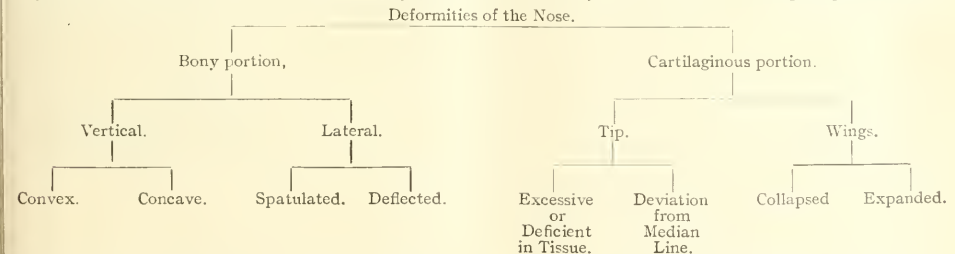
The symmetry of the nose is indeed more important than its size. A nose which is originally proportionate to the face, if deformed by loss or displacement of even a small amount of tissue from any portion will appear very unsightly, while the same nose, made one or two degrees smaller, will, if its different parts are made perfectly symmetrical, have a more or less becoming appearance. The general shape of the nose, also, should be made to conform to the general shape of the face: for example, a sharp, narrow nose would not harmonize with a broad, full face, neither would a broad, full nose harmonize with a narrow, thin face.

In the correction of all facial defects, the surgeon must be not only an artist, but also more or less of a sculptor, with perception of symmetry as related to the different features. How often do we see persons who in infancy had been operated on for harelip and fissured jaw, according to the principles most accurately laid down in surgical works, and who nevertheless present a most disfigured appearance, because of the entire disregard of the principles of proportion or symmetry. This is also the case where operations have involved the corners of the mouth and the eyelids.

A very careful study of each particular case and an accurate planning of the operation beforehand, is as important to insure the success of the operation as is the careful planning of a house by the architect, or of a bridge by the engineer necessary to the success of the finished structure.

In a previous article, read before the British Medical Association in 1888, I classified nasal deformities into two main classes—first, those deformities which affect the bony portion of the nose, and, second, those which affect the cartilaginous portion. The special deformities of the different portions of the nose I subdivided as follows: First, those affecting the bony portion, which may be too convex or too concave, or deflected laterally; and, secondly, those affecting the cartilaginous portion, which may be due to excessive or defective development of the tip; and, thirdly, those affecting the wings, which may be either collapsed or abnormally expanded.*

For convenient reference, this classification can be more clearly shown in the following diagramic form:



There are, however, other extraordinary deformities resulting from injuries or from extensive destruction of the hard or soft parts by syphilis, lupus, or other diseases, which, in many cases, will not admit of classification, owing to the peculiar distortion or extensive destruction of the hard or soft parts. In many cases, however, the method of correcting the deformity by subcutaneous operations is equally applicable and attended with the same excellent results as in the case of those previously

* Read at the annual meeting of the Medical Society of the State of New York, 1905.

* "The Correction of Nasal Deformities by Subcutaneous Operations," *The American Medical Quarterly*, June, 1889.

classified. It is true that in syphilitic cases greater difficulties are encountered and a greater uncertainty as to the result can be expected owing to the tardy healing and instability of the tissues. For the purpose of illustrating the manner in which some of these extraordinary deformities may be corrected by the subcutaneous method, I have selected the following cases:

Case I.—A young man, twenty-seven years of age, was referred to me December 19, 1901, for the correction of a deformity of his nose, which had resulted from being kicked in the face by a horse, on the 21st day of the previous August. The impact of the horse's shoe fractured the bones of the nose, driving the central portion inward, and dislocating the nasal and lacrymal bones outward, and forming a sort of ridge on the outer sides, while the toe cork of the horse's shoe caught the nose just at its junction with the upper lip, tearing up the columna and nearly all the anterior portion of the cartilaginous part of the septum.

The patient was at once sent to a large hospital in a neighboring city for surgical attention. On his arrival at the hospital about the first thing the attendant did, the patient stated, was to cut away the partially detached columna instead of stitching it into place, as should have been done, even though it were so much detached as to have become partially devitalized. Had this been done, the columna of the nose would doubtless have been saved. There have been many cases in which a large portion of the nose has been detached, and in some instances even the whole nose has been severed with a knife, sword or even bitten off, and upon being reattached and stitched on union has taken place. Therefore, under the circumstances, the cutting away of this partially severed portion was, to say the least, unfortunate.

In correcting this deformity, the first step was to restore the upper and external portion of the nose to a symmetrical and normal shape. This was accomplished by transplanting tissue from the thickened and too prominent portions of the nose to the depressed portion, and holding the nose in shape by an external saddle splint until the transplanted portions were united and fixed in the desired position. This was all done subcutaneously, the operation consisting in elevating the skin over the depressed portion by means of an incision made from the inside of the nose, and filling in the depressed portion with flaps of tissue taken from the neighboring parts, these being held in place by the nasal splint until the tissues were firmly fixed in the desired position. When this was accomplished, the important task of restoring the columna and anterior portion of the cartilaginous septum was next undertaken. After considering the various methods devised by different surgeons for the restoration of the columna of the nose, it was readily seen that none of them met the requirements of this case. Of these operations we may mention the principal ones. The earliest was the Italian method. This method consists in taking the flap from the palmar surface of the hand and suturing it in place so as to form the columna of the nose, the hand being held firmly in place until the flap has become united, similar to the Tagliacotian method for the restoration of the nose. The Hunter method is that by which the columna is formed from the skin of the dorsum of the nose, from which a flap is cut, rotated into position and stitched there. The Wood method consists in making a flap from the central portion of the upper lip between the cutaneous and mucous surfaces extending downward to, but not through, the vermilion border of the lip. This flap is turned upward and covered by a flap taken from the cheek on either side. The Diefenbach method consists in making two vertical incisions through the entire thickness of the upper lip, thus making a tongue about one-fourth of an inch in width, which is entirely free except at its upper attachment. This is turned upward and united to the remains of the septum and to the ala at the top by fine sutures. The mucous membrane of the lip, which looks outward in its new position, soon becomes skin on exposure to the air. The cut surfaces of the lip are brought together in opposition and united exactly as in the operation for hare-lip. This last-mentioned operation was the most feasible one in this case; but as the patient was a man the growth of a mustache in the nose would be a lasting source of annoyance to him. In order to avoid this and also the disfigurement that results from all the above described operations, I devised the plan of filling in the gap with a flap of tissue taken from the under side of the upper lip. As the lip was quite thick, we had abundant tissue at our command, but the question was to utilize it without injuring the external skin. I accordingly dissected up a sufficient amount of tissue from the under side of the lip to fill in the gap in the septum, leaving it attached above by a broad pedicle. The next thing was to get the flap in place without carrying with it any of the skin of the upper lip. This difficulty I overcame by buttonholing the upper lip at the point of the former lower attachment of the columna and pushing the flap through this opening. Then by folding this flap inward upon itself, and stitching the cut surfaces together, and the upper end of the flap to the remaining upper stump of the columna and the posterior border to the remaining portion of the triangular cartilage, a complete columna and septum were formed. The edges of the part to which this flap was stitched were necessarily scarified and freshened in order to secure union. This transplanted tissue formed a most excellent substitute for the original septum, and the mucous membrane from the interior of the lip on being turned outward and exposed to the air became very normal appearing skin. The wound on the under side of the lip was closed by stitching the edges of the mucous membrane together, and when healed scarcely any trace was left where the flap had been removed, and no scar where the flap was put through the lip.

Fig. 1.

The union of this transplanted tissue was so nearly complete that only a small perforation at the upper and posterior angle, where the flap was stitched to the septum, remained after healing. This opening was filled with a flap taken from the inside of the left ala, which was somewhat larger than the right and could readily spare it. The flap which was carefully stitched in place by means of curved needles* (devised by me for intranasal work) readily

* For illustration vide article on "The Removal of Obstructions and Cicatricial Contractions of the Nose by the Plastic Method," *New York Medical Journal* and *Philadelphia Journal*, July 30th, 1904.

united, filling the opening completely and leaving the septum in an excellent condition. The wound in the ala, whence the flap had been taken, was closed by stitching the edges of the mucous membrane together, so as to leave no exposed raw surfaces that might possibly result in a synechia.

Fig. 2.

Figs. 1 and 2 of the accompanying illustrations show the nose before the work was begun, and Fig. 3 after its completion. Fig. 4 is from a photograph taken before the injury, which shows the nose to have been of a fine Grecian type. The very nearly complete restoration of the nose to its original symmetry was, therefore, exceedingly gratifying, both to the patient and to myself.

Case II.—Mr. G. H., age thirty, was referred to me January 25, 1902, for the correction of an exceedingly peculiar, and, we might also say, interesting, deformity of the nose, which had resulted from an injury caused, when a boy, by falling on his face upon the ice while skating.

Fig. 3.

At the time of the injury, which was regarded as a comparatively trivial one, little or nothing was done, aside from arresting the hemorrhage and relieving the swollen condition that remained for a few days. When the swelling had subsided, and after he had entirely recovered from the injury, his nose was found to be quite crooked, the deformity after a time becoming very pronounced, as shown in Fig. 5. It will be seen by the illustration that the nose was crooked in several directions—the bridge of the nose being displaced to the left, the center of the nose to the right, while the tip of the nose was turned very much to the left, making a sort of inverted letter S. In addition to this, the septum was distorted in a similar manner, obstructing both nostrils, and the whole nose was deflected to the right about 30°. There was also a nodular projection of the cartilage on each side of the tip, the left being larger than the right and giving the end a peculiarly nobby appearance, somewhat resembling a hammer-nosed whale. In correcting this deformity, it was necessary to refracture and thus to liberate, to a greater or less degree, the entire nose as well as the septum, at the different places, in order to straighten the nose, take out the kinks, and set it straight on the face.

Fig. 4.

In straightening the nasal bones, or bridge of the nose, it was necessary to refracture them both, in order to move the center of the nose over to the right and to make it symmetrical. This was done by an original method, which I had previously devised for this purpose and used on several occasions, in order to avoid injury to the skin, which necessarily results when force sufficient to fracture the bones is applied to the exterior of the nose. This method consists in raising the skin from the bones by an incision made from the inside of the nose. Through this incision one blade of a stout pair of forceps similar to Adam's forceps is passed, and the other blade into the nasal passage. By this method the bones are readily fractured without injury to the skin or visible soft parts.

Fig. 5.

Fig. 6.

In straightening the end of the nose and putting it in the center of the face, it was necessary not only to straighten the septum, but to liberate it from its lower attachment for a considerable distance, so as to be able to set it over where it belonged.

In order to overcome the longitudinal curve in the septum, a vertical incision through the center of the septum just in front of the nasal bones was necessary, which was made in an oblique manner, instead of transversely, so that the cut surfaces could be coaptated and readily held together until union had taken place in its new position. The curved septum, after being liberated, was found to be best held in place by pins, while the whole nose was maintained in a symmetrical shape, and also in its proper position on the face until healed. This was done by a form or saddle splint made of the proper size for the nose and to correspond to the shape desired.

Fig. 7.

The result of these various operative procedures may readily be observed in Fig. 6, in which it will be seen that not only is the nose straight in relation to

itself, but also as related to the face; that is, in its proper position on the face.

Case III.—H. N., age 19, was referred to me on account of a sunken condition of his nose, caused by a specific condition. Four years before I saw him, he sustained a severe injury in an attack from highwaymen, in which he received a horizontal cut across the forehead and a deep cut between the eyes. His nose became greatly swollen and was attended with a discharge of so-called "matter" from the nostrils. After that time for three years he had an almost constant formation of crusts in his nose, which would come away in large masses, often attended with more or less bleeding. In January, 1899, the cartilaginous portion of the nose began to settle inward, wrinkling the skin at the sides and giving the nose a very unsightly appearance, as shown in Fig. 7. On examination the whole triangular cartilage was gone, with ulceration still going on at the base; the nose was full of dried crusts, which were removed with considerable difficulty. The bridge, or osseous portion of the nose, was not destroyed, and consequently appeared in comparison with the sunken portion of the nose, very prominent.

Fig. 8.

Fig. 9.

In correcting this deformity, several things had to be taken into consideration. In the first place, we had no triangular cartilage to support the anterior portion of the nose; and a plastic operation, taking a supply of tissues from the forehead or cheeks, could not be done without leaving a disfigurement, scarcely less noticeable than the present one. Consequently, the only plan that would give the best results with the least disfigurement, if successful, was the transplantation of tissue subcutaneously. This method accordingly was undertaken, and finally, after a number of operations and a great deal of patient care and attention, was a gratifying success.

Fig. 10.

The first thing necessary was the arrest of the ulceration by a course of thorough specific treatment, required by the unquestionable cause of the trouble, which had followed as a sequel and apparent result of the injuries he had sustained from the highwaymen. After this was done, and the ulceration was entirely arrested, I began the work of correcting the deformity. The first operation was to transplant a portion of each nasal bone, both of which were unduly prominent, into the depressed portion between the skin and outer wall of the vault of the nasal passage, thus making this portion of the nose quite symmetrical. This was accomplished in a very satisfactory manner through an incision made from the inside of the nose, in a manner already described in the other cases. The nose during this time was held in position by an external saddle splint and an intranasal support until the parts had become quite firm, there being more or less development of osseous tissue from the periosteum that had been transplanted with the bone removed from the bridge. It was necessary to raise the tip of the nose in order to make the nose symmetrical. The wrinkled and displaced shield cartilages were then incised, straightened out and held in position until reunited. It was then necessary to transplant other tissue to fill in the remaining depressed portion. This was done with tissue taken from the cheeks along the base of the nose. In some instances this tissue was entirely severed or disconnected, but when placed in its new position, with gentle pressure to keep the parts coaptated and prevent any accumulation of blood, the tissue readily took hold and grew without any trouble whatever. This was done at frequent intervals until the depressed portion of the nose was entirely filled in and the walls of the nostrils had become so thick and firm that danger of further settling of the nose had disappeared. Figs. 7 and 8 illustrate the nose when I first saw it. Fig. 9 is from a photograph taken a short time ago and sent to me by the patient.

Fig. 11.

Fig. 12.

Fig. 13.

Case IV.—H. G., age 28, was referred to me by Dr. Roswell Park, of Buffalo, July 19, 1901, for the

correction of a very pronounced and unsightly convex vertical deformity of the nose. In addition to this angular deformity the nose was abnormally long, giving it somewhat the shape of a parrot's beak. This condition was largely congenital, although it had been aggravated by an injury resulting from the patient being thrown from a carriage, which injury had caused more or less of an exostosis of the anterior portions of the nasal bones.

Fig. 14.

The operation for the correction of this deformity consisted in removing the angular projection of the nasal bones and also of the upper lateral cartilage, and shortening the end of the nose.

In removing the angular projection from the dorsum of the nose, great care was necessary to avoid cutting into the vault of the nostrils, which extended quite high up into the projection. In some cases, however, where the top of the nose is very projecting and the vault of the nostrils extends high up into the projection, the cutting through into the top of the nostrils cannot well be avoided. In such cases, in order to avoid leaving a flat surface on the top of the nose after the operation, the outer edges of the bones should be beveled off, and if standing somewhat apart, fractured and turned inward so as to closely coaptate. Should they, however, show a disposition to spread apart, they can be held together by a clamp or saddle splint, or sutured together with silver wire. In performing the operation for the reduction of this deformity, the work is done entirely through an opening made from the inside of the nose as in the other cases, so that the skin remains uninjured.

Fig. 15.

Fig. 16.

The method resorted to by some operators, and that quite recently, of making an incision through the skin along the dorsum of the nose in order to remove this redundant tissue, is not only unnecessary, but inexcusable, since it can be done so well from the inside of the nose subcutaneously, without the necessity of the unsightly scar, which ordinarily follows the cutaneous incision.

After the performance of this operation, the nose is best dressed by applying gentle pressure by means of a saddle splint to keep the skin in immediate contact with the parts below, so that almost immediate union takes place. The shortening of the nose is accomplished by resecting a portion of the lower part of the triangular cartilage large enough to allow the end to recede sufficiently to make the nose symmetrical; the edges are then stitched together with fine silver wire, or horsehair sutures. In this case the result was highly satisfactory. Fig. 10 illustrates the nose before the operation and Fig. 11 the result.

Fig. 17.

Case V.—Miss G. R. C., of Richmond, Ind., age 16, was referred to me July 21, 1904, for the correction of a concave vertical deformity of the bony portion of the nose, commonly termed "saddle-back nose," that had resulted from an injury sustained eight years before.

Fig. 18.

While attending a picnic, when eight years old, in running across some benches, she fell, striking her nose on the edge of one of the seats, fracturing the nasal bones. The nose bled profusely at the time, and soon afterward became much swollen, this being accompanied by considerable fever. On account of the marked swelling of the tissues, the fracture was undetected until this had subsided. By this time it was thought that the bones had become too firmly fixed in this depressed condition to render any successful attempt to correct the deformity possible. This deformity, furthermore, became much more marked as the child grew older and the development of the face took place. The nasal passages, however, were not obstructed, so that mouth breathing has not been necessary, and her health has been good.

On examination it was found that both nasal bones also had been dislocated outward, forming a distinct ridge on each side. The seasamoid cartilages in the dorsum, however, were driven inward, leaving the central portion, or bridge of the nose, flattened and almost level with the face, as shown by the accompanying illustrations, Figs. 12 and 13. The end of the nose was quite prominent

Fig. 19.

and somewhat bulbous, making a very pronounced pug. The first operation consisted in dessecting up and raising the skin from the nasal bones, through an intranasal opening, and sawing off, together with the periosteum, their projecting portions, hollowing them out so as to give to the sides of the nose their proper contour. These bone flaps were then carried up to the center and placed together in the median line, their bases being applied to the top of the sunken portion. After these parts had healed, a flap was made from each side of the bulbous portion of the end within the nostrils, extending down nearly to the border of the meatus. These flaps were turned upward into the depression caused by the sunken and partially destroyed sesamoid cartilages and held in place by an external nasal splint until the parts were all united in the desired position. This left the nose in the shape shown in the photographs, Figs. 14 and 15, taken six weeks after the operation and just before the patient left for home.

Fig. 22.

Case VI.—Mrs. Viola W., age 42, the wife of a physician, brought to me by her husband November 23, 1904, for the rectification of a very crooked nose and a badly deviated septum, causing almost complete nasal obstruction.

When about 9 or 10 years old, while playing with children at school, they making chairs with their hands and carrying each other in this manner, she fell forward to the ground, striking on her nose. The bleeding was so profuse that she was taken as soon as possible to a physician. By this time her nose had become so swollen that the fracture which had occurred was undetected. When the swelling had subsided, however, the nose was found to be quite crooked, and the deformity grew more pronounced as she developed, having increased even during the past few years.

On examination of the nose externally, there was found to be a convex vertical deformity of the bony portion, which was also deflected to the right. There was a marked depression at the osseocartilaginous junction and the end of the nose was very much bent to the left, as is shown by the illustrations, Figs. 16 and 17. On examination of the septum the osseous portion proved to be greatly deflected, turned to the left, obstructing the left nostril, while the osseocartilaginous portion was deflected to the right, obstructing the right nostril, the end of the cartilage being again deflected to the left, thus forming a letter "S" septum.

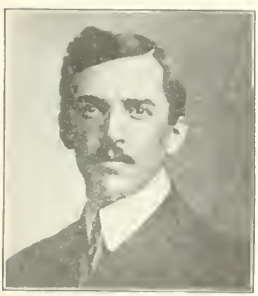


Fig. 21.

In correcting these deformities, it was necessary first to straighten the septum and to place the end of the nose in the median line. This was done by the method which I have devised, with the aid of my fenestrated comminuting forceps. In a few days, when the septum and the end of the nose had become fixed in a perfectly straight position, the angular portion, projecting to the left from the bridge of the nose, was sawed off obliquely, so as to give the bridge its proper contour, and the bone flap thus formed was placed in the depression at the osseocartilaginous junction. This flap fitted into the depression so nicely as to give the dorsum of the nose a perfectly regular contour, and, being held in position until firmly united, left the nose in the condition shown in the accompanying illustration, Fig. 18.

Case VII.—Mr. R. A., age 30, was referred to me by Dr. Goodale, of Boston, May 16, 1904, for the correction of a very serious deformity of the nose, which had resulted from specific infection contracted five years before. Three months after the infection there was an eruption; one year afterward a sore throat; three years afterward ulceration of the throat and nose. In May, 1903, there was a necrosis of the bridge of the nose, causing a perforation of the skin at about its center, just to the left of the median line. In about three months this opening healed with cicatricial tissue, leaving a cup-shaped depression and an opening through into the posterior nares, about the size of a lead pencil, which had resisted all attempts thus far made to close it.

In correcting this deformity, the first desideratum was to close this opening in order to have an unbroken skin so that the transplantation of tissues to fill in the depression could be done entirely subcutaneously. In closing this opening the skin was carefully raised from this cup-shaped depression and the citatricial tissue removed by a longitudinal elliptical incision; the edges of the skin being carefully sutured together so that when healed there was nothing left but a slight linear scar. When the parts were thoroughly healed, the projecting exostosis, the result of the previous ulceration and periostitis, was sawed off in such a manner as to correspond with the normal contour of the nose, by the method described in previous cases. These tissues were then placed in the depressed portion and held in place by the writer's nasal splint until healed, thus giving the bridge of the nose its normal shape. In the left ala there was a mass of thickened tissue, the result of the previous ulceration. By means of an incision from the inside of the nose, I made a flap of this tissue and turned it into a depression existing at the osseocartilaginous junction. It was necessary to perform two or three minor operations in a similar manner in order to fill in other depressions and irregularities. The result was a nose normally symmetrical in every way, with only a slight scar on one side of the bridge, which might readily be attributed to a Heidelburg students' duel. Figs. 19 and 20 show the nose before the work was begun, and Fig. 21 the result.

The form of dressing that has given me the best results has been a saddle splint of the desired shape and size, made to fit the nose after the deformity is corrected, held in place by adhesive plaster across the face. This form of dressing I first devised for the treatment of fractures of the nose and afterward found it to serve a most admirable purpose as a retentive instrument in the correction of the various nasal deformities.

It is, of course, necessary to remove it frequently and change its shape, as the swelling that follows the operation subsides; but it should be worn until the tissues are firmly fixed in place.

It is needless to say that in the performance of these operations the strictest aseptic precautions must be observed, for suppuration in the wound beneath the skin would not only defeat the purpose of the operation, but lead to a further deformity, possibly more unsightly than before.

With the exercise of skill and ingenuity and the most careful attention to details, we are able to relieve patients of a condition which would remain a life-long mark of disfigurement, constantly observed, forming a never-ceasing source of embarrassment and mental distress to themselves, amounting, in many cases, to positive torture, as well as often causing them to be objects of greater or less aversion to others.

It will be a surprise to any physician, who will take the trouble to investigate the subject, to find how many brilliant lives, how many noble personalities, and how much valuable talent have been, so to speak, buried from human eyes, lost to the world and society, by reason of the embarrassment and mortification caused by the conscious, or in some cases, the unconscious influence of some physical infirmity or deformity or unsightly blemish.

The effect upon the mind of such physical defects is very readily seen reflected in the face, which invariably conforms to the mental attitude, and leads after a time to a permanent distortion of the countenance.

The influence of the emotions, or the mental state, is manifested not only in the facial expression, but in the disturbance and derangements of the bodily functions and, as is well-known, and frequently observed, in the condition of the general health; the effect of the latter in turn may also be reflected in the facial expression.

The face is composed largely of muscles, but, unlike other muscles having only bony attachments, many of the facial muscles at one end terminate in or are attached to the skin, all being more or less closely bound together by fibrous connective tissue. These muscles are of the voluntary type, though controlled involuntarily by the condition of the mind; and their correlative activities are manifested by the particular form of the face and wrinkling of the skin characteristic of the different emotions. Thus each thought or emotion, disease or derangement, sending its own particular message to the different muscles, causes a distinctive expression peculiar to each particular thought.

If the mind is possessed of a certain dominant thought, whether of joy, gladness, sorrow, worry, or anxiety, the face gradually assumes and retains the corresponding expression by reason of the constant pull of these muscles both on the soft and hard parts, the latter finally yielding more or less to the continued tension.

Thus it is that habit of thought becomes fixed in the expression, and one skilled in interpreting the anatomy of expression can at once read in the face the habitual mental state.

The ordinary conditions affecting the mind—whether external and due to domestic, social, or pecuniary causes, or internal and due to the condition of the health or bodily functions—may change in character or degree, or disappear altogether; but to a sensitive person, a striking physical defect or deformity is an ever-present source of mental discomfort. If it be a facial deformity the characteristic mental attitude is not only manifested in the physiognomy, but this expression thus acquired will in turn still further add both to the facial disfigurement and to the mental distress.

44 Clinton Avenue South.

## ACTINOMYCOSIS OF THE LUNG.*

By E. FLETCHER INGALS, M.D.,
CHICAGO.

Actinomycosis of the lung is a rare affection, yet, all told, many cases have been reported. It is most frequently observed among men who have had the care of stock that have been affected by the disease, yet not infrequently, as in a case that I have to report, there has been no contact with actinomycotic cattle, and the infection occurs from very obscure sources.

Although rare, the disease is frequent enough that general practitioners, especially in the country, should be on the lookout for it lest they fall into errors in diagnosis.

As an introduction to this subject, I wish briefly to recount the history of a case that recently came under my observation through the courtesy of Dr. Emanuel Senn and Dr. C. Volini.

The patient, an Italian, A. M., 22 years of age, came to this country about two years ago, and shortly after his arrival went to work on a railroad in Minnesota, near St. Paul, where he worked for nine months, and then returned to the city, where he remained three months, and then again resumed his work on the railroad. In Italy he had lived upon a farm, doing an ordinary farm laborer's work and taking care of some stock. Since coming to this country, while working on the railroad he lived on the construction train and slept on a straw bed, the tick of which had been filled with straw procured from a neighboring farmer. The farmer had cattle, but it is not known that any of them were sick; however, the workmen were not likely to be informed on this subject. On the 18th of last November the patient took a handcar and went to the city, where he spent the evening eating and drinking. On his way back he said that he took cold, and on going to bed he felt a good deal of pain in the back. The next day he was able to do only half a day's work on the railroad, and the following day was obliged to give up his job. Since that time the pain in the back has been present most of the time. The patient has steadily failed in strength and weight, and upon admission to the hospital, on February 27, he appeared languid and weak. He felt obliged to go to bed because of the weakness and because he had less pain and felt better when quiet. He has not been troubled with cough any of the time. His history shows that he has been a moderate user of alcoholics, tobacco, tea and coffee. He has never suffered from any illness, so far as can be ascertained, and the hereditary history is good. The father and mother, two brothers and nine sisters are all living and well. So far as he knows, there has never been either tuberculosis or malignant disease in the family. Upon admission to the Presbyterian Hospital (Chicago) he was complaining of some pain in the right side, more particularly between the right scapula and the spine. His skin was sallow, countenance anxious, the sclera moderately icteric, mental condition apparently normal. He formerly weighed 150 pounds, but on admission only 124 pounds. The temperature ranged from 99° to 100° F., pulse from 98 to 120, respiration from 24 to 30 per minute; blood contained 56 per cent. of hemoglobin, leucocytes 16,850 (Zeiss count). The voice was weak, but he had no dyspnea, and there was no other evidence of pulmonary disease. The tongue was clean, appetite fair, digestion good, bowels somewhat constipated, urine negative. There were no abnormal signs in the upper air passages.

*Read before the Nebraska State Medical Society at Beatrice, Neb., May 3, 1905.

An examination of the chest showed a swelling about 8 cm. in diameter in the right interscapular space extending from the spine to the inner border of the scapula and extending from the third rib above to the seventh rib below. This swelling was raised at its highest part about 2 cm. above the normal surface of the back. The skin about the border of the swelling was firmly attached to the underlying tissues, and there was very little motion possible. Over the center of the swelling fluctuation could be detected, and there the skin was loose and movable.

Dr. C. Volini brought this patient to the hospital and placed him under the care of Dr. Emanuel Senn, who made an incision over the swelling, from which about a teacupful of grayish pus and blood clots escaped. A counter opening was also made about two inches below, drainage established and healing by granulation encouraged. In the pus were many small yellow granules about the size of a pin's point, which upon microscopic examination proved to be the actinomycosis fungi.

When Dr. Senn called my attention to the case, he did not feel certain whether the abscess communicated with the pleura or not, but was inclined to think that it did. Upon my examination of the chest, I found the form and movements normal. Two small wounds which had been made by the surgeon were found in the right interscapular region. The physical signs in front over the lungs and heart were entirely normal. Posteriorly, I found moderate dullness at the right of the spine, extending from a level of about 2.5 cm. above the spine of the scapula to the level of its inferior angle, and from the spinous processes of the vertebræ outward about 2.5 cm. beyond the inner border of the scapula. In this region the vocal fremitus was somewhat diminished, but not entirely lost. The vocal resonance was not altered; however, the respiratory sounds were very indistinct; no râles could be heard. All other portions of the chest yielded normal signs. In the drain from the wound I observed a yellowish granule about 2 mm. in diameter. This was placed under the microscope and found to contain typical actinomycotic fungi.

This is far from being a typical case, but it serves the better to impress upon us the need of great care in the diagnosis of diseases out of the usual course.

*Anatomical and Pathological Characteristics.*—Actinomycosis of the lungs is a chronic inflammatory affection characterized by the production of linear and tortuous tracts of necrosis and softening and the formation of fistulæ connecting a greater or less number of these foci with each other or forming drains from these to the surface or to internal cavities. This disease tends to extend in different directions, and to involve the various structures with which it comes in contact. The structure of the lung and its great vascularity conduces to frequent termination of this disease in fibrous induration and shrinkage of the pulmonary parenchyma, so that advanced cases often present great flattening and immobility of the chest, like that seen after some attacks of chronic pleurisy, or in pronounced cases of fibrosis of the lung.

In advanced cases of the disease, the lesions are so complex that it is often impossible to classify them with any distinct anatomical form; but earlier nearly all cases fall with the pleuropneumonic or the bronchopneumonic varieties.

In pleuropneumonic actinomycosis, the invasion occurs from without. The pleural layers when attacked become thickened and irregularly adherent to each other, forming pockets in a part of the pleural cavity, which at first contained serum and fibrin and later pus. The underlying lung becomes pneumonic and softened in spots or irregular linear tracts, through which the burrowing tracks of necrosis undergo liquefaction and form fistulæ which communicate with the various foci or the pleural pockets. By extension, some of these finally break through the bronchial walls, and we then have superadded the bronchopneumonic form of actinomycosis. The inflammation involves the bronchial walls and the peribronchial tissues extending along the course of these tubes and resulting in linear consolidated areas. The areas soon present yellowish softened centers corresponding to the lumina of the bronchial tubes.

The lung in this condition closely resembles tuberculous bronchopneumonia. As the process extends the parts first involved tend to undergo cicatrization resulting in grayish or bluish white fibrous bands the lung tissue between which is softened and infiltrated with mucopurulent secretion in which the little yellow granules characteristic of actinomycosis can be found. Some of these granules are almost microscopic, others are two or three m.m. in diameter. These granules may often be satisfactorily examined when magnified with a low power of only 100 diameters.

When cicatrization is less advanced, the peribronchial embryonal or granulation tissue has a reddish or bluish red color, while the softened centers of the obstructed bronchi are yellowish. The older lesions are often seen in the upper part of a lobe, while more recent and smaller lesions occupy the lower part.

Sooner or later the two forms of the disease run into each other; the pleuropneumonic extending inward until the bronchi are involved, or the bronchopneumonic progressing outward until the pleura is affected. When the process first attacks the pleura a sero-fibrinous inflammation occurs in the part involved which soon causes adhesions resulting in pockets in the pleural cavity which at first contain serum but later pus. This burrows along the softened tracts where there is least resistance resulting in fistulæ by which the pockets may communicate with each other, with the surface, with the bronchi, or with fistulæ or small cavities in the internal organs.

The post-mortem appearance will depend upon the mode of invasion, the extent of the process, and the results of the secondary infections. In advanced cases, the processes of consolidation, softening, cicatrization, and contraction are so confusing, that it is often impossible to determine the variety of the beginning of the disease. In this disease the bronchi become plugged with epithelial cells from the lining membrane and with leucocytes, and there is marked cellular infiltration of the walls and peribronchial tissues. Necrosis and fatty degeneration occur in the central portion of these tracts and thus small abscesses are formed which contain actinomycelial kernels. Similar processes occur in the alveoli which are at first filled with fibrin and cellular exudate. Necrosis, however, is not so prominent a feature of this process as cell proliferation, consequently a rich vascular embryonal tissue is formed about the bronchi in which hemorrhagic points are common. This tissue tends to form limiting walls about the abscesses.

The proliferative changes cause thickening of the alveolar walls. In the contracting process that follows the alveoli are apt to become oblong and their epithelial cells to assume the cuboid form. Unlike the resolution after pneumonia, in the softening and necrotic process in actinomycosis the alveolar walls are themselves destroyed, but the resulting abscesses are small, instead of resembling those of pulmonary tuberculosis; hence, the respiratory signs usually differ considerably from those of the latter disease.

The bronchi and alveoli may also be occluded by the fibrous tissue growing inward from without. When healing takes place the actinomycetes become calcified. Microscopic examination even with low powers will reveal the colonies of Ray fungi or branching threads with bulbous ends, but these are better shown when magnified from 1500 to 2000 diameters. (See the illustration.)

*Etiology.*—The affection is usually caused by the inhalation of vegetable particles that find lodgment in some portion of the air passages, but it may be due to invasion from the buccal cavity, the pharynx or cervical region, or to direct involvement by extension of the disease from the mediastinus, the esophagus, the liver and diaphragm, the vertebræ, or indeed any of the surrounding strictures. It sometimes results from metastasis through the blood vessels.

In the case that I have recorded the disease is of the pleuropneumonic variety and the invasion appears to have been from without. The confinement of the process to a single focus, the absence of an earlier variety and the freedom of the bronchi from disease leads us to conclude that it could not have resulted from the inhalation of the actinomyces. Owing to the fact that the first evidence of the disease

Ray or Actinomycosis Fungus, magnified about 1500; A, fiber masses; B, club-shaped forms; C, dark areas intersected by loose fibre complex; D, dark nuclear areas; E, lighter marginal nuclear areas; F, fiber bundles greatly magnified.

was found on the back, between the scapulæ, and that the physical signs clearly indicate involvement of the pulmonary parenchyma, without any appreciable involvement of the bronchi, the question arises whether this invasion could have occurred through the unbroken skin or through some forgotten scratch or pimple or other slight lesion.

The ultimate cause of the disease is the ray-fungus, but it is not produced by a single parasite, for there are a number of varieties of the ray-fungi and several of these have been found in the lungs in actinomycosis. The changes found in these organs in advanced cases of this disease do not all result from the actinomyces, but some of them depend upon a mixed infection with bacteria, particularly the pyogenic cocci.

*Symptomatology.*—The symptoms of the disease vary greatly in different cases and are seldom typical, but this very atypical character is of much value in forming a diagnosis. In the pleuropneumonic variety the patient may only complain of a sense of weight or constriction of the chest or simply vague thoracic pains and of poorly defined functional disturbance; or he may suffer with acute pain as in pleurisy. These pains are usually constant, but as in the case I have related they may be slight and intermittent. If the pain girdles the chest it indicates that the intercostal nerves or their branches are compressed. Gradual and often steadily increasing emaciation and weakness mark the progress of the disease, but sometimes the process is temporarily or permanently arrested.

When cavities form, the progressive anemia, emaciation and night sweats are like the symptoms in consumption. According to the amount of lung tissue involved, to the extent of obstruction in the bronchi, or to the degree of weakness, the respiration becomes quickened, and when the bronchi are affected there is a harsh cough which is usually dry. Hemorrhage occurs only rarely. The sputum that is raised is of a mucopurulent character and usually offensive, but not so offensive as that of bronchiectasis or gangrene. The pulse is somewhat increased in frequency but usually much less than in pulmonary tuberculosis. The temperature, although increased, is less so than in the latter disease, and in some cases the temperature early is much like that of typhoid fever. These symptoms are necessarily much modified by secondary infection with pus cocci.

The intercostal spaces over the diseased pleura may be edematous. Percussion and auscultation furnish evidence of more or less thickening of the chest wall or consolidation of the lung or of both, sometimes with islands of nearly healthy lung tissue surrounded by the diseased tracts. In the pleuropneumonic variety, thoracentesis may yield a thin serous, a serofibrinous or a purulent fluid, which is likely to be obtained from two or more comparatively small pockets. The fluid may be lustrous, pearl-colored, or hemorrhagic in appearance, or it may be a thick yellowish or grayish pus.

In the bronchopneumonic variety the disease commonly attacks the lower lobe of the lung first, causing symptoms much like those of chronic bronchitis and yielding on physical examination areas of dullness with islands or patches of normal resonance and râles and bronchial signs like those of bronchopneumonia. When cavities form the whole symptomatic picture may very closely resemble that of pulmonary tuberculosis, but in actinomycosis the cavities are usually quite small so that they may not yield very distinct signs.

*Diagnosis.*—This disease is liable to be mistaken for pulmonary tuberculosis, gangrene, malignant disease, syphilis, and hydatid cysts.

An accurate history often aids greatly in the diagnosis, but finding well marked ray-fungi in the sputum settles the question. Often the branching ray-shaped fungus can be detected with a low power (1-100). The sputum or fluid withdrawn from the chest should be diluted with distilled water and the yellow kernels allowed to settle. Some of this sediment should be stained by Gram's method, but it may be necessary also to stain a control slide by Erlich's method, as these fungi are destained by acid, while branching tubercle bacilli that are sometimes found are not. The slides should be examined with both low and high-power lenses.

The bronchopneumonic form is distinguished from infectious diseases complicated by pleuritis or pulmonary disease by the chronicity of its course by its usual limitation to certain parts of the lower lobe of the lung, by the sputum being at times streaked with serofibrinous, or purulent, in actinomycosis, and by the fact that the physical signs in this variety of acti-

nomycosis are usually much less than would be expected from the gravity of the constitutional symptoms.

The pleuropneumonic form is distinguished from pulmonary tuberculosis, in many cases by the continuous pain, by the fetid sputum, and by the absence of hemoptysis and the signs of cavities.

It is distinguished from gangrene by the history, by less fetidity of the sputum and milder symptoms, and by absence of cavity signs.

It is distinguished from cancer of the pleura by the history, by the character of the exudate, which is generally sanguinolent in cancer but only serous, serofibrinous or purulent, in actinomycosis, and by the presence of the yellow kernels in the latter disease. The speedy return of the exudate when aspirated, the pain and the cachexia are much alike in the two diseases.

Syphilis of the lung may closely resemble this disease. The differential features are found in the history and in microscopic examination of the sputum. The iodides may be beneficial in either disease, therefore the diagnosis cannot be established by the results of treatment.

Hyatid cysts yield some symptoms and signs that might be mistaken for those of actinomycosis but the serum withdrawn is not coagulable by heat and nitric acid in the former, while it is in the latter, and the microscopic findings in the latter are characteristic.

*Prognosis.*—The cure of this disease can be hoped for only when it is recognized early. The normal duration has not been determined, but some cases seem to have terminated within two or three months, while others have lasted as many years. Recovery may take place, but after apparent recovery the disease may again become active. When the disease in the lungs results from metastasis through the blood vessels, from foci in other parts of the body, or when metastasis has occurred from the lungs, recovery cannot be expected. When extensive softening and burrowing have occurred, the prognosis is very grave.

*Treatment.*—In the treatment of this disease good hygienic conditions such as light and sunshine, fresh air and proper clothing and housing and good food are, of course, to be obtained if possible. Tonics are also recommended, but it cannot be shown that any of these appreciably modify the course of the disease. Iodide of potassium has been found useful in the treatment of the disease in cattle, and it has apparently been beneficial in combating the early stages of the disease in man. From 30 to 90 grains daily should be given and good effects may be expected in early cases that are progressing slowly, but the medicine can have but little influence when secondary infection with pus cocci occurs. C. J. Ochsner (Annals of Surgery, April, 1905, p. 633) states that about 90 grains should be given three times a day. That many cases are not apparently improved at all until these large doses are reached.

Surgical measures should be adopted when it is practicable to remove the diseased tissue or in the evacuation of collections of pus and the numerous adhesions between the pleural surfaces renders this an attractive field for operation, but unfortunately the tendency of the process to extend so widely in various directions renders it difficult to eradicate the diseased tissue; however, a combination of surgical and medical treatment is indicated in many cases with the hope that the iodides may cure what cannot be reached by the knife.

34 Washington Street.

## POISONING BY WOOD ALCOHOL.

### A CASE OF COMPLETE BLINDNESS (TRANSITORY), WITH RECOVERY OF VISION.

By CARL KOLLER, M.D.
NEW YORK.

The knowledge of the poisonous properties of wood alcohol, and especially of its deleterious effects on the vision, is of very recent date; in fact, it is within only about five years that it has become generally recognized by the medical profession. Of the fifty-four cases collected from literature and tabulated by Buller in his and Casey A. Wood's valuable monograph on "Poisoning by Wood Alcohol" (read at the Fifty-fifth Annual Session of the American Medical Association, in 1904), only four cases antedate the year 1899. These four were respectively in 1879, 1888, 1897, and 1898. The other fifty cases were published between 1899 and 1904. Upon inquiry instituted among the profession in the United States and Canada, Wood has been able to add one hundred and eighty-one cases of partial or complete blindness, blindness followed by death, or death without history of previous blindness—all of recent years. It is very likely that sporadic cases occurred in former years (and were perhaps attributed to other causes). The present alarming increase in blindness and death caused by poisoning with wood alcohol is due directly to refinement in its manufacture by which it is rendered odorless. The nauseous odor adhering to the product by the old process limited its use to purposes of the arts and trades, for instance, as a solvent of shellac, etc.; and although poisoning by the fumes occasionally did occur, poisoning by drinking was quite out of the question.

Since an odorless product under the name of "columbian spirits," "colonial spirits," or "eagle spirits" has been put on the market, its uses have been largely increased, and not only its legitimate use, but it has to a very large extent entered into the adulteration of alcoholic beverages, into the manufacture of flavoring substances meant for consumption, and into the preparation of proprietary remedies in which only ethyl alcohol should have been used. Many cases of blindness and death have followed the ingestion of Jamaica ginger, lemon extract, essence of lemon, essence of peppermint, bay rum, Cologne water, witch hazel, etc.

The sensation produced in this city quite recently, through the sudden death of a considerable number of men (variously stated at 17 to 25), in a certain district, who had fallen victims to the consumption of whiskey adulterated with wood alcohol, is still fresh in everybody's memory. Under these circumstances, the publication of the following case, which presents some interesting features, appears sufficiently justified.

S. G., a Russian Hebrew, forty-two years of age, presented himself on October 28, 1904, at Dr. I. Abrahamson's clinic for nervous diseases in the Mt. Sinai Dispensary. He was totally blind, but perfectly rational. He had no idea what had caused his condition, and the history which he gave lacked, therefore, the most important element. He stated that he used tobacco and alcoholics very moderately, drank tea excessively, and enjoyed, in general, very good health, occasionally suffering from rheumatic pains. There was no history of syphilis.

He was referred to the eye department for an examination of his eyes, and, the true state of affairs being here suspected, the following history was elicited from him:

On Saturday, October 22, after the morning service, he took at the house of some friends a small

quantity (about two ounces) of whiskey, but did not feel anything unusual until after eleven o'clock in the evening. When returning home from a meeting which he attended the same evening, he felt chilly and nauseated, and vomited. He drank some tea and went to bed. The next day (Sunday) he went, according to his every-day custom, to morning and also to evening service, but neither ate nor drank. During the night he woke and noticed that the gaslight seemed dim. On Monday morning he rose at seven o'clock and as it appeared rather dark to him he asked if it was raining. Then he noticed that his vision was at fault, but ascribed it to his abstaining from food the previous day, and drank some tea. He could not read the ordinary print of the newspaper although he was able to distinguish the large letters. He felt chilly and extremely weak and his hands were cold. As the day wore on, vision became worse, but toward evening of the same day he could indistinctly see, though not recognize, human figures. On the next morning (Tuesday) he was completely blind, all perception of light being gone. Various physicians were consulted but the condition remained unchanged. Total blindness persisted for the following four days. On Friday, October 28, he came to the Dispensary. The status præsens was as follows:

"The pupils are widely dilated and absolutely without reaction. The optic nerves of both eyes present the picture of a neuroretinitis of moderate intensity. The outlines of the discs are indistinct; the radiating nerve fibers are opaque and somewhat edematous; the blood-vessels (arteries and especially the veins) congested. In the macular region of both eyes are dispersed numerous yellowish, bright-shining little spots, similar to the picture described as choroiditis guttata."

On his way home from the clinic he saw with his right eye the first ray of light. This caused him to change his attitude toward our request for a sample of that whiskey of which he had partaken two days before the visual disturbances began, and at a subsequent visit he brought a quantity of it sufficient for chemical analysis. Dr. Carl Goldmark, chief of the Dispensary pathological laboratory, made a qualitative test which showed the presence of methyl alcohol in the whiskey. As the test is very decisive and easy of execution, it might be useful to describe it in a few words. Dr. Goldmark says regarding it:

"The test depends upon the synthetic production of methyl salicylate (artificial oil of wintergreen). Beringer devised the method of producing methyl salicylate by taking half an ounce of salicylic acid, dissolving it in two ounces of absolute methylic alcohol, and then gradually adding one ounce of sulphuric acid. On this basis the whiskey was tested. To about two drachms of the suspected fluid, half a drachm of salicylic acid solution and one drachm of sulphuric acid were added in a test-tube. The odor of the oil of wintergreen was at once apparent, and became more pronounced the longer it stood."

Later, Dr. S. B. Bookman, of the Mt. Sinai pathological laboratory, made a quantitative analysis of the sample by fractional distillation, and found that it contained 34 per cent. of pure methyl alcohol. Our patient had therefore taken about 20 c.c. of pure methyl alcohol.

Potassium iodide was prescribed and the patient was directed to take hot baths to induce free perspiration, and to nourish himself well. As a result of this course of treatment there was a gradual improvement in vision for the following two months. He did not present himself for an eye examination until December 21, when sent for; but on November 18 we heard of him, that the right eye had steadily and rapidly improved since the day of his first visit, and that the left eye had begun improving about two weeks later. When he was examined on December 21, the vision of the right eye was 15/20, and that of the left 15/30. The outlines of the fields of vision were normal. The ophthalmoscopic examination showed a decided change. The discs were well outlined, and in their temporal halves very pale. The big vessels showed no abnormal caliber, perhaps the arteries were somewhat narrower than they should have been. The bright yellowish spots in the macular region of both eyes were decidedly increased in number.

The patient was lost sight of until sent for at the end of April, that is, six months after the onset of the affection. His examination on April 23, 1905, gave the following result: The pupils were more than average size, about 6 mm. in diameter, in an ordinarily bright room. When his face was turned toward the strong light of the window, they became slowly narrower, 3 mm. in diameter. The reaction to strong changes of light was very sluggish. The vision of the right eye was 4/12 and with +1 sph. cyl. +0.5 ax. hor. it was 4/8, this improvement of the vision with a convex correcting glass in a man of forty-two years, who had not used glasses before, evidencing a weakness of the accommodation which is in keeping with the weakness of the pupillary reaction. The vision of the left eye was 6/36, the refraction the same as in the right eye, but the glass caused no improvement. The field of vision of the right eye was normal in its outlines, no relative central scotoma. The field of the left eye showed moderate concentric contraction (about 15 degrees); no perception of green color; red recognized, and no relative central scotoma could be ascertained with this color. The ophthalmoscopic examination showed the optic discs opaque and very pale, bluish, edges fuzzy; lamina cribrosa visible; arteries narrow, especially those of the second order; those of the third order were hardly visible. A connective tissue sheath accompanied the arteries a short distance from the nerve head. The veins were larger than usual, especially in the left eye. The retina was very thin, appeared atrophic. In the macular region of either eye were very numerous yellowish-white dots.

That methyl alcohol is a poison dangerous to eyesight and to life is now generally concerned, although not long ago it was disputed, sincerely by some and from interest by others, the chief contention being that not the methyl alcohol itself, but admixed "impurities" produced the poisonous results. Of such, acetone was chiefly accused. The uncertainty was largely due to the fact that taken in small quantities methyl alcohol is innocuous to a great many persons, although taken in large quantities or habitually in moderate quantities it must be acknowledged as poisonous without exception. On the other hand, there are a great many people for whom a very small quantity (half a teaspoonful) would constitute a dose sure to bring on the gravest consequences. This difference, or "idiosyncrasy," well known in regard to every poison, in the case of methyl alcohol is most likely due to the difference in secondary chemical compounds formed in the alimentary canal and in the blood of the different persons by whom it is ingested. One of these secondary compounds is formaldehyde, but whether it is or is not the chief factor of methyl alcohol poisoning is not decided.

In reviewing all the cases on record, Casey A. Wood comes to the conclusion that there are three

degrees of wood alcohol poisoning: "(1) An ordinary, mild intoxication, with perhaps some dizziness, nausea, and mild gastrointestinal disturbance, terminating in perfect recovery within a few days, but occasionally followed by more or less serious damage to vision. (2) A toxic effect more pronounced in every way—dizziness, nausea, and gastroenteritis being conspicuous symptoms. Dimness of vision, often increasing to total blindness, is characteristic of this degree of poisoning. (3) An overwhelming prostration which terminates in coma and death."

The most conspicuous and characteristic feature of wood alcohol poisoning is complete bilateral blindness, appearing sometimes suddenly, but in most cases gradually after a period of failing vision. The disturbance of vision will sometimes come after a few hours; in most cases it lasts from one to several days, until a dimness of the sight is noticed. (In the case above reported it took about forty hours.) This progresses until the blindness is absolute. The interval between the ingestion of the poison and the onset of the eye symptoms is very characteristic, and may in some cases, as for instance in ours, hide the real cause of the blindness from the patient. The blindness lasts for a period of several days or even weeks, after which sight returns gradually. The improvement is frequently very considerable, sometimes full restoration takes place; but the improvement is not lasting. After several weeks the vision begins to fail again, and in the great majority of cases this progresses to final and irreparable blindness. Very few cases preserve useful vision; early treatment seems to be favorable to this termination.

Of the objective symptoms the only one constant from the beginning is widely dilated pupils without any reaction whatever. The ophthalmoscopic picture varies. Either it is entirely negative and thus corresponds with the usual assumption of a retrobulbar neuritis, or it shows a papillitis or neuroretinitis of low degree—slight swelling of the nerve-head, blurring of the outlines, radiating appearance of the slightly edematous nerve fibers, and congestion of the large blood-vessels, especially the veins. This condition was present in our case in a rather marked degree. A third variety shows pallor of the disc from the onset, with contracted blood-vessels, so that, although not so intense, it is similar to the appearance in quinine poisoning. But whatever the picture in the beginning, in all cases we ultimately find atrophy of the optic nerve and retina, an extremely pale, bluish or grayish disc with outlines distinct but fuzzy; the large blood-vessels, especially the arteries, contracted, for some distance contoured by a connective tissue sheath; no smaller blood-vessels or capillaries visible— in a word, the picture of postneuritic atrophy. Nowhere do I find mention made of the presence in the whole macular region, of the yellowish, bright spots described in the above case. I might consider them an accidental circumstance if I had not once seen the same condition in a man whom I treated for alcohol-and-tobacco amblyopia.

The field of vision shows anomalies in all cases. It is nearly always concentrically contracted, and generally there is an absolute or relative central scotoma present. In our case, after six months the right eye showed complete recovery of function (except a moderate diminution of the acuteness of vision), probably owing to the small amount of poison ingested and the early institution of treatment. The left eye showed marked although moderate concentric contraction of the field, considerable diminution of central vision, and absence of perception of the green color. A central scotoma for other colors at that time could not be established.

As to the pathology underlying these visual disturbances, opinions are divided, some ascribing it to a retrobulbar neuritis, whereas others believe that the ganglion cells of the retina are the structure primarily affected, followed by ascending—or, rather, descending—atrophy of the optic nerve fibers. The writer is inclined to accept the latter view, although it must be admitted that a number of weighty arguments can be adduced for either of them.

With regard to the course of therapy to be followed in a case of wood-alcohol poisoning, sweating by hot bahh or pilocarpine, potassium iodide internally, and sufficient diuresis (perhaps by means of a milk diet), suggest themselves as rational, and have been successful in some cases.

The utmost importance belongs to prophylaxis. The public in general must be enlightened as to the poisonous nature of this substance, and laws should be enacted forbidding its use in the manufacture of "essences" and proprietary remedies which may be the means of poisoning persons not addicted to the use of intoxicating drinks and who are entirely ignorant of the danger to which they are exposed.

---

## SOME ASPECTS OF THE CANCER PROBLEM.*

By G. BETTON MASSEY, M.D.,
PHILADELPHIA.
ATTENDING SURGEON, AMERICAN ONCOLOGIC HOSPITAL.

The first step in the solution of a problem is a full realization of the pressing nature of that problem. That this step has been taken in connection with the cancer problem is evident from the widespread interest in the subject shown by the recent medical literature of all countries. In America we owe this awakening to Dr. Roswell Park, whose prediction concerning the increase of cancer in this country, made some years ago, is in a fair way to be verified by the facts. In Philadelphia, for instance, the ratio of cancer deaths to the population has increased from 314 per million in 1881 to more than 700 per million in 1904.

With 1,037 deaths from cancer in this city during the past year, we must have had at least three thousand persons suffering from this affection during the same time—a most appalling state of affairs. The mere statement of such figures, which are paralleled and even exceeded in other portions of the country, should arouse to renewed effort a profession whose practical relation to the subject is illuminated by the broadest altruism.

The aspects of the cancer problem that I will briefly review this evening will not include a discussion of recent investigations into the nature of these affections. The time has not yet arrived for any but the research workers themselves to estimate the results attained. My remarks will be confined to ascertained facts and accepted views alone, in the belief that we are already possessed of more information in the premises than is generally acted upon.

I shall therefore speak briefly of (1) *The importance of a wider diffusion of our present knowledge concerning cancer.* Though there is much yet to learn concerning this affection, even possibly its true nature, and certainly the method by which it attacks its victims, yet we are in possession of most important information of a definite character concerning it. That much of this information is totally misun-

* Read before the Philadelphia County Medical Society, May 10, 1905.

derstood by the people, to their dire disadvantage, is evident by their total disregard of its cardinal points. We know, for instance, that cancer is purely local in its first manifestations, and that the only constitutional feature present in this curable stage is a possible non-immunity to it. That this fact is not understood by the sufferers themselves, is evidenced by general disregard of the early manifestations of this disease—a disregard and misconception that must be shared by some misguided physicians themselves who have given the advice, "Don't touch a cancer until you have to!" I do not believe that any physician would be guilty of this ignorance at the present day. It remains a fact, however, that a former ignorance on this subject has been most unfortunately absorbed by the general public. It should be our duty to enlighten the people on this point, whether we were formerly responsible for such errors or not, and urge the scientific value of the earliest destruction of suspicious nodules, and the deplorable results of a policy of delay, permitting a general diffusion of what was at first a strictly local malady until it is changed into a general infection.

We should inform the public that all painless, growing nodules are suspicious nodules, and should be submitted at once to the scrutiny of a physician. The common belief is that nothing can be cancerous unless painful—an unerring evidence of a disregard of all stages of these growths but the last one.

We should also do all possible to dissipate any tendency to ostracize these sufferers by assuring the public that all scientific testimony is against the possibility of the ordinary means of infection spreading these diseases.

(2) *Who is responsible for the present neglect to inquire into the causes and methods of prevention of cancer?* The opportunity to serve mankind in establishing the cause and proper means of prevention of cancerous affections will most likely be the lot of a member of the medical profession: that body of men whose daily work itself sows the seed of altruism in the heart of each individual member, if he be not altogether absorbed in love of self. In spite of this probable fact, it is an error to assume that the public may safely wait with folded hands until some brilliant physician, without special assistance, discovers the cause of cancer. Research of this nature has no possible means of remuneration within itself, and the hope for the glorious result will not pay the living expenses of the devotee, who is, apparently by an economic law of human effort, invariably poor. If the general government maintains a meteorological service for the problematic prediction of weather conditions; an agricultural department for the benefit of the farmer; a most extensive service for the benefit of the mariner; nay, even an army and navy for the general defense—surely it should provide the living expenses of workers and the other costs of a research into the cause and prevention of this affection, with its increasing menace to the life of the citizen. Such, indeed, is the need, uncertainty of results, and importance of this work that state governments should establish additional and independent laboratories of research, while the field would not be crowded if a score of financial giants each endowed an institution for this purpose.

The responsibility for this work is therefore in the hands of the public itself, and can be transferred to professional hands only with the provision of ample means for its prosecution.

(3) *What positive and negative indications for treatment we have at present?* The history of medicine records many instances where an efficient remedy has been applied to a disease long before the true nature of the disease has been understood. Striking examples of this are the discovery of the value of cinchona in malaria four hundred years before the exact nature of this affection was understood, and the discovery of the value of vaccination one hundred years ago, while the germ of smallpox is still under judgment.

Whatever the true nature of cancer, we can positively affirm that nearly 100 per cent. of external and semiexternal cancerous growths can be positively cured in their early stage by the destruction or removal of the original nidus of the disease. This cannot be said with equal truth of many affections regarded as trifling ailments, yet whose course can only be watched and assisted.

Such is the curability at its inception of these growths that the appearance of one on the body surface should be likened to the arrival of a ship infected with cholera at the maritime port of a country. The general system of the patient may be as surely protected from its dissemination as the country is protected from cholera by the disinfection of the ship and the isolation of its passengers.

Early and complete destruction of the primary growth is then the scientific remedy for cancerous growths, and if this simple plan be followed at the right time, the need for the discovery of an effective toxin for vaccination, or of an antitoxin for combating the disease, will be confined to internal primary growths alone—a very small proportion of the whole—for, to turn to a homely illustration, what practical gardener would care to inoculate his garden with a weed toxin or antitoxin when the patch of weeds is so small and circumscribed that he may pluck them out at once, root and branch? Even the detterent action of the *x*-rays would be unnecessary if the aroused sense of the public would bring these growths under treatment in their earliest stage.

Early removal or destruction being so effective, it is our duty to ascertain why so few sufferers present themselves in this stage. The fact that they go to the quacks and irregulars shows that a belief in its constitutional nature cannot account for all the neglect of early treatment, for the quack methods are usually of a purely local character. The obvious answer is that curettage and enucleation of these growths have been failures because these procedures permit a reimplantation of the cells or germs in the disturbed edges and open lymphatic vessels, while complete and wide removal is dreaded as too severe an operation, in spite of the fact that this is the only time at which it is an effective cure.

That a wide-sweeping knife operation may cure one of these small cancers on the surface, and is therefore a scientific procedure, is unquestionably true; but the attitude that neglects the value of cauterization, particularly the electrochemical methods of destructive sterilization, and clings to the knife as a panacea is anything but scientific.

It is the writer's belief that if a more judicious use were made of the cataphoric, or electrochemical method in these early and small growths, a very large percentage would be permanently cured, and without pain or material scarring, while the exercise of a wide discretion in the choice of remedies suited to the case would invite earlier resort to treatment by these sufferers, thus additionally increasing the percentage of cures.

Finally, no physician should attempt to handle these cases unless he determines to apply to them the most earnest and painstaking care. To merely operate on such a case and then lose sight of the patient is reprehensible. At the American Oncologic Hospital we have adopted the rule that all patients discharged apparently cured must return weekly for inspection during the first six months and monthly

thereafter for a year, whenever possible. By this constant oversight the earliest sign of a possible recurrence is noted and promptly destroyed, enabling us at times to snatch a brilliant success from what would otherwise have been a lamentable failure.

## THE TREATMENT OF SPASTIC CONSTIPATION.

By A. ALBU, M.D.,
BERLIN, GERMANY.

Chronic constipation, as is known, belongs to the most frequent diseases of the digestive system, being a disease of daily occurrence and affecting the poor and the rich, the young and the old. Although it does not at all spare the male sex, the female sex suffers for more from it. We may really say that this disease accompanies man from infancy to death. There are innumerable people, who evidently get through with the trouble year by year, without ever asking any medical advice at all. To a great extent these people continuously help themselves with the use of laxatives, being obliged to change them every couple of weeks and months, on account of their becoming ineffective. Perhaps the frequency of the disease, and the insignificance of complaints have been the prime reasons why clinical research formerly did not devote attention enough to the pathology of constipation. It was a general rule to regard chronic constipation as an atony of the intestines, and especially an atony of the muscular coat of the large intestine was mostly supposed to be the cause of the inactivity of the intestines. In the predominant majority of cases of chronic constipation this pathogenesis still proves perfectly true. In the last two decades, however, we have known a second form of chronic constipation, which on closer examination proved equally significant: the spastic constipation, which, contrary to atonic constipation, does not depend upon an atony, but rather upon a spastic contraction of the intestinal wall, especially of the musculature of the large intestine. The literature on spastic constipation has markedly increased during the last years, and according to my own experiences I must agree with the opinion of other authors to the effect that this form of constipation is found the more frequently, the more carefully it is sought for. Especially in the female sex a not unimportant percentage, I would estimate at least 25 per cent. belong to this form of constipation, and many of the most persistent cases of chronic constipation, refractory to all methods of treatment, even to intelligent, energetically and consistently maintained measures, do not improve for this very reason, that the treatment depends upon an erroneous supposition. Numerous cases of apparent atonies of the intestines, depend upon spastic constipation. As the treatment of the latter, as we will see, is diametrically opposed to that of atonic constipation, it will hardly be wondered at that such cases are treated for years without success.

The differential diagnosis between atonic and spastic constipation is often extraordinarily difficult, sometimes entirely impossible. In the following all the indisputable facts shall be discussed as briefly as possible. Spastic constipation affects chiefly very neurasthenic or even hysterical individuals, who show various general or local symptoms of this primary disease. They mostly are weak, insufficiently nourished, somewhat pale individuals, in the third or fourth decade of life; in the predominant majority females. Amongst the neurasthenic and hysterical symptoms they show there is sometimes a spasm in the automatic musculature, for instance pharyngeal spasm (globus), the cardio spasm, the pyloric spasm, and so forth. The spasmodic contraction of the intestinal musculature occurs at intervals, the duration being very variable. An attack may last for hours, days, and even weeks, but with frequent, more or less protracted interruptions, durwhich the intestine is atonic. Undoubtedly atony is the base upon which the spasm develops. In the syndrome of neurasthenia the development of a spasm of the automatic musculature on the base of an atony is of daily occurrence. Voluntary spasm of atonic muscles also occurs frequently; I refer to the spastic contractions of paralyzed limbs. Many patients feel the spasmodic contractions of the intestine as an indefinite oppressive sensation in the abdomen, which, however, sometimes increases to colics. In reality this spastic constipation is nothing else than the intestinal colic of chronic saturnism, caused by the incrustation of the musculature of the intestine with lead, which irritates its motor nerves. Also in ileus and in chronic stenosis of the intestine the constipation often is caused by a secondary spasm of the intestinal musculature, situated above the obstacle, and moreover dynamic ileus is exclusively dependent upon spasm of a more extended portion of intestines, this fact being best proved by the successful atropine therapy so much recommended recently. The spastic contractions of the musculature are by some patients also felt in the rectum and in the arms, so that they have the sensation of their feces being violently retained.

Corresponding to these subjective sensations of spastic contraction there is in many cases the positive proof of contracted intestinal knots, especially in the right and left portion of the lower abdomen. For the cecum on the one hand, and the sigmoid on the other hand, are the chief sites of spastic contraction, as well as of atony. In the former case one feels either continually or temporarily at the places mentioned sausage-shaped structures of about the size of the small finger and equally long, or even longer, which can easily be moved to and fro, of elastic consistency and very sensitive to pressure. It may be emphasized that the contraction of the cecum often gives rise to confusion with other sensitive resistances in the ileocecal region and often simulates a chronic appendicitis. Owing to the grave prognostic and therapeutic indications of the latter condition, such a mistake must be seriously warned against. The diagnosis is often reached, especially in dubious cases, by digital exploration of the rectum, which also demonstrates spasm in the sphincters, as the examining finger is closely grasped by the convulsively contracting sphincters. In some cases the spastic constipation is on the whole limited to this most inferior portion of the intestines. As a complication also of this form of constipation enteroptosis is not rarely met with, especially a coloptosis, the transverse colon then running at the level of the umbilicus from one hip to the other as a long, solid cord of a finger's breadth, and so-called membranous enteritis, which, according to Nothnagel's opinion, in the majority of cases, is to be regarded as a motor neurosis of the intestines (colica neurosa), and therefore closely related to spastic constipation.

For diagnosis finally the condition of the feces also is of value. In general they are, as in atonic constipation, dry, hard, and scanty. Sometimes they assume the characteristic shape of a ribbon, or of a flattened lead pencil, on account of the incarceration of feces in the spastically contracted intestinal knots. This form was formerly called stenotic feces, and has been regarded as characteristic of chronic

intestinal stenosis. This opinion, however, has for a long time been acknowledged to be erroneous. The so-called stenotic feces, very often absent even in mechanical stenosis, do not prove more than that a constriction exists somewhere in the intestines, usually a spastic one. In many cases of spastic constipation, it is true, the feces do not show any peculiarity.

The reason why I have entered into more detailed particulars of the symptomatology and diagnosis of this form of disease, fully explained in recent times by Westphalen (Petersburg), G. Singer (Vienna), and others, is, because all the forms of treatment that are to be mentioned here can be founded only upon a most perfect knowledge of the syndrome of the malady.

As the spasms develop on the basis of atony, it is obvious that every occasion for exciting them must carefully be avoided. Every irritation of the intestines and, above all, massage, which is often extraordinarily effective in atonic constipation, must be avoided. Therapeutic efforts, moreover, have to be directed to an improvement of the irritative condition, similarly to the calming of excited waves. For this purpose the following measures prove suitable: (1) The use of warm, or, better, hot baths which can be prescribed as sitz, or complete baths (at a temperature of 30-35° R. and a duration of 15 to 20 minutes); (2) the application of hot compresses to the abdomen, which not only mitigate the spasm, but also relieve the painful sensations and colic. Whether dry or moist dressings are used makes no difference. The use of the thermophor proves very suitable; (3) warm enemas of linseed oil, sesame oil, or also of castor oil in a quantity of one-quarter liter every day in the evening, given in bed with the buttocks raised, or in the knee-elbow position, whereby deeper penetration and a prolonged retention of the oil is guaranteed. It is not a question of producing immediate bowel movements by the enema, for the oil is to act as a sedative on the spasm of the intestinal musculature and should therefore remain in contaction with it as long as possible. The injections should be made as slowly as possible and with only a slight pressure, preferably with a big syringe or with a glass funnel; (4) as the best antispasmodic atropine or belladonna is recommended, the latter as the extract in the form of suppositories, in the dose of 0.2 g.-0.3 g., two to three times daily; (5) concerning the diet used in spastic constipation the opinions of expert authors differ very much. Some of them recommend a diet as bland as possible, while the others on the contrary advise heavy, vegetable food. According to my experience both opinions are erroneous. I have found a vegetable diet the best, the food being most carefully freed from all hulls and shells and so forth—that is, from all cellulose which might irritate the intestinal wall. By such a chiefly gruel-like diet on the one hand the excitement of intestinal spasms will undoubtedly be avoided, while on the other hand the atonic inactivity of the musculature is counteracted. Such patients, therefore, may be allowed to take all sorts of wheaten bread, made of fine flour, greens in form of prunes and cooked fruits. Soups and broths are also allowed. The use of milk, in quantities of 1 liter, is very advisable, if it does not constipate the bowels in the individual concerned. Alcohol, spices, cabbage, cucumbers, celery, radishes, cheese, and so forth, must be strictly avoided; (6) the introduction of solid hard rubber or wooden bougies into the rectum, which remain in position every day 10 to 15 minutes. They should be lubricated with oil and be introduced 5-10 cm. The use of these bougies is especially indicated in the above mentioned cases, and they are very useful, where a spasm of the sphincters is found.

I cannot recommend the advice of some authors who, prescribing for these patients long and continual rest in bed, because by this means the primary atony of the intestine is favored. On the contrary, exercise in the fresh air will mostly do those patients good. Only in very weak, very debilitated and also in intensely hysterical persons a regular fattening cure is recommended, which not only increases the strength, but also restores the natural mobility of the intestine. To this cure, radically disturbing their private life, the patients can be persuaded only after all other means have been tried in vain. Then, of course, this attempt is fully justified, and to the surprise of the physician and the patient very often achieves a striking success.

## INEBRIATE MANIAS: A MEDICOLEGAL STUDY.

By T. D. CROTHERS, M.D.,
HARTFORD, CONN.
SUPERINTENDENT WALNUT LODGE HOSPITAL.

The following cases have a practical as well as a medicolegal interest, and reflect a confused recognition of facts in the profession that is deplorable. These cases are by no means unusual, but the great prominence of the victims and the physicians who were called to give advice make them conspicuous object lessons that should never occur in our present knowledge of the subject.

A lawyer of great prominence, actively engaged and living a regular life, although probably overworking, became suspicious of the fidelity of his wife. This became so offensive that his wife consulted a leading physician, feeling sure that some mental change had taken place in her husband's mind. The physician remonstrated with her husband and tried to show him the error of his belief. Later the husband advised with another physician, equally prominent, who assured him that this was a delusion. He then applied to a detective agency, and after months of the most careful watching, they reported that his suspicion was unfounded. He believed that the detective was in league with his wife, and determined to act as detective himself. Armed with a revolver, he spent most of his time in hunting up imaginary trails, the failure of which only convinced him more firmly of the subtlety of his enemies. In the meantime he pursued his professional work with his usual skill and acumen, and seemed in no way different from his usual manner.

He confided to his family physician his determination to shoot anyone under any suspicious circumstances. The physician advised a change and visit to Bermuda. This he did, insisting on going alone and secretly. He returned on the next steamer in the most secret way and was recognized in a room overlooking his residence in a neighboring house, and explained his presence as a mistake. He then went to the club to live.

His wife became alarmed, as he had threatened her life. Two physicians examined him carefully, and decided that they could find no reason for his strange conduct, also that there was no evidence of insanity. As to the delusion of his wife's infidelity, they gave no opinion, but would not sign any papers certifying to his impaired mental condition.

Fearing a homicide, his wife left secretly for a distant part of the country, and he went back home to live. He was still under the impression that she came to the house and was admitted from time to time. Acting on this belief, he shot at a servant girl one night, slightly injuring her.

He was examined again by two physicians, and his explanations were so plausible and his conduct so rational that they could give no opinion other than that he was sane. From the facts submitted to me for an opinion, it appeared that for at least ten years he had drank large quantities of strong spirits every day, both at home and at the club, drinking at regular intervals, and never seeming disturbed or confused from their use. He conducted his business with the usual skill. The only change noticed was dullness, particularly in the latter part of the day, his mind working more slowly, and the usual optimism giving away to criticism and doubts of the honesty of others.

The last two years the amount of spirits had been taken at shorter intervals, and he had slept more, sometimes retiring in the middle of the day for an hour or more. There was no evidence of specific disease. He was very regular in all his habits, had no bad associates, and had lived on the most amicable terms with his wife up to the time this delusion began. Both were exemplary persons. His wife was a church member and moved in the best society. My opinion that this was an alcoholic mania and that he should be declared insane at once and confined in an institution, was treated as absurd. The absence of any other symptom except this delusion was evidence to his physician that his mind was yet sound. He was finally persuaded to take an ocean voyage with some friends. He disappeared from his berth one night and was never seen again. Whether he committed suicide by jumping into the sea, or fell overboard, it was not known.

A will was found leaving all his property to his wife, and no reference was made to this delusion in any of his papers. The possibility of a homicide was averted only by the good sense of the wife, who realized her husband's irresponsibility more clearly than the physicians, and kept out of the way.

The second example of a similar case was that of a brother of an eminent physician who had accumulated a very large fortune by careful methodical work. For the last ten years of life he had drank spirits at meals and before retiring. His conduct and habits were unchanged. While he was recognized as sometimes being under the influence of spirits, his mind showed no change in the affairs of everyday life.

Suddenly, without occasion, he became convinced that his wife was untrue to him, and accused her in the most violent way. She had a family of three children, who joined with her in the injustice of this charge, and tried to persuade the father that he was wrong, but failed. For over a year this condition existed, the accusations being made oftener, and finally accompanied with threats. The wife remained in the house for weeks, hoping to allay his suspicion, which grew more intense with every effort of hers to show its falseness. Two physicians, with his brother, were appealed to, and after a careful examination, they declared it a family quarrel, in which there was no sign of mental disturbance on the part of the man. They declared that they both needed rest and a change, and urged them to go on a long tour to the West. After some persuasion the wife consented, and they went away, apparently reconciled. Ten days later they were both found dead in a bed at a hotel. He had evidently shot her while asleep and then killed himself. The matter was concealed from publicity, but the friends from whom these facts were obtained considered that his brother and the physicians had made a fatal mistake in not recognizing the insanity of this delusion and having him confined at once.

In the third example which came under my observation, a man of wealth, after drinking half a lifetime in so-called moderation, suddenly became convinced that his wife was plotting to destroy him, and was unfaithful. He concealed this delusion for a long time. His suspicions were revealed by his rushing in unexpectedly to his wife's room with a revolver in his hand, and looking through all the closets and under the bed, as if suspecting some concealed intruder. Later he openly accused her, and threatened great violence. Then, for the first time, he became wildly intoxicated on the way to Boston. His condition was so offensive that he was brought to my place for temporary care.

The question of his normal condition was brought up, and two physicians, one who had been in the family for years, and the other an expert neurologist, decided that he was not irresponsible or in any way insane, that the delusion of his wife's infidelity did not have an alcoholic origin, and that his present condition was owing to malarious complications and business difficulties. My opinion that these delusions would lead to a homicide unless he was confined and the spirits withdrawn was not shared in by his counselors. Two weeks later, in great excitement, he rushed into a neighbor's house, saying that he had shot his wife and a man he had found in her company, and would have to spend the rest of his life in a prison, or die on a gallows. Before he could be prevented he shot himself and died the next day.

It was found that he had gone downstairs secretly from his room, and seeing his wife talking with a grocery clerk, had shot at them. As they both dodged under the table he concluded that he had killed them. In the neighboring house where he went it was announced that in taking out his pistol to show it to a friend it was accidentally discharged and caused his death.

These three cases bring out clearly the great danger of permitting anyone to be at large entertaining delusions of this character, particularly where they have an alcoholic origin. The fact should be recognized that delusions of this class are evidence of an advanced stage of neuronic degeneration, and are very marked in persons who drink. They may not always concern sexual relations, but become delusions of persecution and intrigue to destroy character, property, and jealousy to prevent success in business, in politics, and in society.

Thus, a man of some prominence who drank steadily believed he was surrounded by envious intriguers who secretly sought to prevent his success in every possible way. Later he believed that his wife and family had been bought to be untrue to him and to desire his death. Suspicions of poisoning, next to sexual infidelity, are common in alcoholics and inebriates. These delusions are very dangerous and point to a degree of mental failure and inability to reason rationally that is likely to end in homicide from the slightest exciting causes. Whenever a drinking man or drugtaker becomes possessed of these delusions, he should come under public notice and care as a dangerous man, and should be placed under control at once.

In the first case I have mentioned, the physicians who doubted the irresponsible condition of the person did not realize that this delusion was alcoholic in origin. They could not understand how irresponsibility could exist in this one direction and apparent full recognition of his condition on other matters be present. They conceived that moderate drinking could not in any way impair his sanity and never be manifest in wild conduct and thought.

In the second case, much the same reasoning prevailed, although there were marked delusions of persecution, and the physician considered these of minor

importance, which a journey among strangers would break up, and his advice to the patient to go away with his wife was fatal.

In the last case it is difficult to understand why the medical advisers should have overlooked the stage of excitement and erratic conduct, together with the delusions, as mere transient conditions, particularly when they occurred in an alcoholic person.

It is very evident that in each of these three examples the medical men utterly failed to realize the gravity of the conditions present, and, in some measure, they were directly responsible for the consequences which followed. In contrast to this is the following: A contractor, of wealth, who had for many years drank spirits steadily, although a man of excellent judgment and kindly disposed, suddenly took on this delusion, and began to threaten his wife. In other respects he was perfectly clear. His family physician realized the situation and secured a commitment as insane. This was questioned, and from the opinion of myself and others the commitment was allowed to stand. After a three months' residence in an institution, he returned home greatly improved and resumed business. A year later he relapsed, and the old delusion returned with greater intensity than ever. He was committed again to an institution, where he is at present. Had the opinions prevailed, as in the former cases, this man would have committed a homicide and have suffered the death penalty. The wisdom of this course is evident from the fact that with the removal of alcohol and restoration of a degree of health the delusion disappeared, and he was able to resume business again.

These overlooked and unstudied delusions are often illustrated in the tragic deaths of persons found in hotels in large cities, who come from inland towns and register at the hotel with some strange woman, and are both found dead in the morning. One such man, who was a steady drinker for years, and who had the characteristic delusions of marital infidelity on the part of his wife, which his friends could not break up, came to New York drinking heavily, and finding some poor woman took her to his room and shot her; then, partially realizing his own condition, committed suicide. All the facts pointed to a pronounced delusional condition which his family physician and friends should have realized long before.

Many of these unexplainable alcoholic homicides start from alcoholic degeneration of the brain centers, and are veritable psychoses of the most dangerous character, requiring prompt, active treatment, and all stupid, timid efforts to determine the degree of responsibility are fatal to the cure and prevention of the case. The rule should be first to determine how far and to what degree the person uses alcohol. The steady drinker is undoubtedly more degenerate and has greater impairment of the higher nerve centers than the periodic drinker. The cumulative effects of alcohol, even in small quantities, are for more serious than a profound intoxication.

A periodic drinker has free intervals of sobriety, during which a certain reparation takes place, but in the steady drinker, no matter how small the amount used, the constant accumulation of toxins permanently disturbs both the nutrition and elimination of the body. One who has drank steadily for years is almost certain to have at some time some significant symptoms of both mental and physical impairment, such as delusions, manias, and psychoses of various forms.

When the delusion becomes well organized and persistent, it indicates a very serious neuronic change; often the manias which appear after long periods of continuous drinking are the first symptoms of paresis, and go on without break or change unless the spirits are removed, and even then the disturbance continues in some form. It is a very safe inference, which experience will confirm, that all delusions, manias, and hallucinations which come on gradually or suddenly in an alcoholic indicate irresponsibility, and call for decisive measures of care and control.

No person in this condition should be permitted to continue business and enjoy full liberty as a sane man. He may not commit a capital crime, but is liable to do damage in some way or other, either to himself or others. Recently such a man committed forgry, overdrew his account, and destroyed the company that he was interested in, giving as a reason certain schemes and projects which other members of the firm were trying to bring about to his injury. This was literally a delusion of persecution, and grew out of an alcoholic degeneration that was overlooked at the time.

Some of the facts that I wish to make prominent are these: (1) The continuous drinker of spirits in active life is cultivating a soil for the growth and development of distinct psychoses, which may break out at any time. One of the most common of these symptoms is delusions of infidelity. They are practically symptomatic of the particular cause, alcohol. (2) Delusion of persecution and delusions of grandeur, together with manias of various kinds, are natural sequels of alcoholic degeneration and should receive the most careful study. (3) All such persons are irresponsible—to what degree the facts of each case will determine. The medical man should recognize this condition and be emphatic in his statements, and never minimize or neglect to recognize the gravity of these states.

## ADVANCED SCHOLARSHIP AND MORBID MENTAL CONDITIONS; SOME CLINICAL CASES.

By WILLIAM LEE HOWARD, M.D.,
BALTIMORE, MD.

By "advanced scholarship" I mean in this article the position attained by men who have followed a post-graduate course, taken their doctorate degree of philosophy, and are either holding professorships or trying to continue further their special work of investigation. This is rather an awkward explanation, but necessary for a full understanding of what follows.

That certain predispositions toward particular lines of study are the symptoms of a neurotic state seems probable from my clinical experience. The following cases did not have their morbid mental conditions brought about by overstudy, dissipation, or excessive worry, but their early inclinations were sown on an unrecognized psychopathic soil and the subsequent studies and thoughts were the easy channels for the psychic flow of energetic mental application. Or, to put it paradoxically: it appears as though it were the psychopathic conditions that direct certain individuals to work hard along the lines of their least mental resistance.

The life of a student of Romance languages, of poetry and literature, while involving strict mental application, studious habits, and constant work, yet does relieve the individual from contact with more practical men, physical work, or physical contests. Such a man's associates in university, college, or society, are apt to be students of the negative humanities. In his school days he will be found to be a boy who always stands well with many of his teachers, but who is an unenthusiastic spectator when his schoolmates play their games or have contests

with rival schools. There seems to be a physical inertness in his movements, and he will avoid, if possible, gymnasium work. He is generally a high-stand man in both school and college.

It is much easier to understand the conditions I refer to by taking a few clinical cases which have come under my personal supervision the last few years. Generalities of these morbid psychic conditions are always interesting, but not always convincing. The only case in this university group that demonstrated any abnormal sexual phases I have described elsewhere,[1] and for obvious reasons leave out of this clinical résumé.

Case I.—H., aged 43; now professor of Romance languages in an Eastern college, came to me while he was pursuing post-graduate work at Johns Hopkins. He realized he was on the road to mental and moral ruin through periodical attacks of uncontrollable impulses to drink—dipsomania. His birth, environments, and education were of the best, except that he was born at a time when both parents had been for a year or so under great mental and physical strain. The father was in constant danger of being assassinated, the enemy's troops were harassing his home, and the prospective mother was at no time able to get away from fear and insults. H. has a borther and two sisters who were born before the Civil War; all are normal and successful in life. He studied abroad for several years, and while he enjoyed the life and habits of Continental students, never felt any impulse to drink to excess, nor had he any impulses he could not control. Nevertheless, I am inclined to think that even the social glasses he indulged in had some effect in bringing into activity the instability of his nervous organization.

H. was 37 years old when he first came to me. He was despondent, melancholic, and discouraged. His position at the university was hanging by a thread, and if he had another attack of the "periodic insanity," as he rightly called it, he would kill himself. It is not my purpose here to describe that "apprehensive depression" (Kraepelin), which is the prodome of dipsomania, or discuss this disease, but to describe a certain group of individuals belonging to a psychopathic class which is ever liable to some form of impulsive act. Dipsomania I have fully explained and described elsewhere.[2]

When H. came to me his attacks occurred about every three months, and lasted from five days to two weeks. He was placed under treatment, and as he gave me every possible assistance, was soon confident of his ability to be successful in life. At the end of five months I left him to himself, as I was obliged to leave Baltimore for the summer. About a month after he had an attack. When he recovered at the end of three weeks he found himself hundreds of miles away, among strangers and with no recollection of how or when he left Baltimore. I kept careful control of him the next winter, and he was able to do good work at the university. He has been free from the uncontrollable impulses for three years, the proof of which is that he has held his position in a small town where the first drink taken by one of the staid college professors would be hailed from housetop to housetop as a beastly, lecherous and drunken orgy. H. has, however, to be careful to see that normal elimination is constantly active.[3]

Case II.—G., aged 46. Graduate of Columbia University. After graduation he went into Wall Street, where he remained several years. After making and losing a fortune or two he took up at Johns Hopkins University a post-graduate course in the Romance languages. He received his doctorate degree.

G. has always been a student; even amid the rush and excitement of Wall Street he found time in the evenings to pursue the study of laguages and literature. His history is good. His father was a rigid Puritan, and brought up the boy in the puritanical atmosphere. His mother was a dreamer and inclined to occult matters. She would secretly talk to her son about theosophy and other cognate subjects which seem to attract women of half-baked intellects.

When G. went to college he was imbued with a belief in mysteries, and had effeminate longings for soul matings and Mahatma meetings. He did not join in college sports, nor did he have the adolescent male energy for athletics. In this nugatory physical manner he passed through college. When he was in Wall Street his environments were such that his latent virility was brought to the surface, and apparently he did not differ from other men in the Street. He now began to take a cocktail before dinner, and in a year or so he was taking a "bracer" at noon. In the course of time he was taking his several drinks a day, and while he never went the "pace that kills," yet he was constantly under an artificial psychic and physical stimulant. One day he left his office in a dazed condition; felt, he says, as if he were walking through a mental fog. The next day he tried to attend to business, and drank more than usual, as he tells us the fear that was over him was terrorizing, and he drank to suppress it. The mental cloudiness continued to increase, the terrible fear of self he could not shake off, and his nights were sleepless and occupied by introspection of sin and poverty. He went away to the country and the seashore and gradually recovered his health. Meanwhile he had become a convert to the Roman Catholic Church. He was and is happily married. When he had recovered sufficiently to think clearly and reason well, he decided that any further activity in Wall Street meant mental ruin. He returned to his studies and entered Hopkins. He worked hard for his degree, was temperate in all things, enjoyed the society of intellectual and musical people, and saw a bright future, as he was slated for a professorship in a well-known university.

A short time after obtaining his degree he began to get sleepless, lose weight, and the old fear of mental disease worried him. He went to the seashore for the summer, where the symptoms remained unchanged, except for a constant loss of weight. He returned to Baltimore in the autumn, looking unlike himself. Thin in body, trembling in limbs, furtive glances, and shambling gait were the physical signs he showed. Mentally, he was wavering in reasoning, had faulty orientation, concentration and application impossible, fear of self constant, and despair had reached a desperate stage. He cried frequently when he told me that Dr. A and Dr. B had pronounced him incurable, that his brain was diseased. His religious ideas and theories ran riot; he was cursed, damned, and only fit for Hades. His past sins were too great to be forgiven, nothing could purge him of his awful, unpardonable sins. He began to despise his body, and would formulate conceptions of purity and impurity; he would repeatedly utter Buddha's lament: "From the sole of the feet to the crown of the head, to the limit of the brain, he saw that the body was born in impurity, came from impurity, and always let itself be drawn to impurity," and would conclude with: "What wise man, having regarded his own body, will not see in it an enemy." He would then tremble, cry, go on his knees and beg me for "God's sake to save his mind, and if I could not do that give him a lethal dose of morphine." It was pitiable to see this one-time mentally strong man now a mixture of hysteria and

melancholy. (Of course, I am speaking of objective symptoms only.)

G. had great faith in hypnotic suggestion, and as part of the suggestive treatment I agreed with him that this method would accomplish our object. Whatever else suggestion did, it certainly enabled me to get him to carry out in detail my advice, and to see me twice a day; the control of these conditions being the most difficult things we have to contend with in these neurotics when there is a mental riot in full activity. He was placed, stripped, on a lounge, and suggestions made that he was suffering from an accumulation of autotoxic material, and when this was eliminated he would be well. I massaged the regions of the liver and that organ. I placed him on purgative waters and a non-proteid diet. As he began to get confidence in himself I had him work in the gymnasium and take cold shower baths. For the insomnia I used hypnotic suggestion. For months this treatment was continued. G. now weighs 220 pounds—he is six feet tall—has better mental vigor then ever, and, what is most important of all, he knows how to keep in good mental and physical condition.

It might be asked why I personally massaged G. Because it is the personality of the physician that makes the difference between success and failure in these cases. Your constant suggestions, their appreciation of your interest, your mere presence, in fact, does most to restore their hope, without which factor they are seldom cured.

Case III.—N., aged 32. Took his baccalaureate degree, also his degree of Doctor of Philosophy, at Johns Hopkins University. His family history is excellent. N.'s whole life has been spent in hard work as a student. He devoted no time to athletics or the usual college sports, living at home with his parents during his whole college and university work with the exception of the period he did some advance work in European universities. He held the chair of English in a Northeastern university until about a year ago, when he was obliged to give up the work on account of mental hebetude and depression. For several months he was tossed between the diagnosis of organic disturbances in the cortex and the advice which is always the display sign of ignorance: "Go away; don't think about yourself; don't worry," etc., *ad nauseam.*

I found him very much depressed, mentally despondent. There were symptoms of melancholia and the abulia was marked. His whole life looked to him a failure, his future darkness and debility. His success in life and his living depended upon his mental activity, and now that had ceased. He could not concentrate his attention on any subject for ten consecutive minutes. The reading of the simplest paragraph was impossible. When he tried to remember what he read, the knowledge that he could repeat a few of the words yet could not convey their meaning to himself brought a depressed condition that had been diagnosed as maniac depressive insanity. There were no horrible introspective hours, no fear of past sins, no religious hysteria—conditions we saw in the last Romance scholar—but a simple humble resignation of the fact that he had a useless mind.

Physically, N. has a large frame, and his constitution has never been injured in the slightest by the use of wine or women. But he had been dissipated all his life, and this dissipation was the cause of the breakdown. His dissipation was in the form of constant mental work and neglect of body. With his large frame, large organs, and natural lung capacity—about one-half of the latter was constantly allowed to remain idle—it was to be expected that autotoxic material should be stored in his system and that oxygenation was constantly far below the needs of the body. For this latter condition I had him take deep breathing exercises in the open air. He was put on eliminants, sent to the mountains for the summer, and advised to study for a short time every day. A steady diarrhea kept up for several weeks, but as it appeared to be constantly of a biliary character it was allowed to continue. He improved slowly for the first two months, after which his mind became clearer and hope entered where fear had so long remained. In four months the former mental vigor returned, and he is now doing good work at the university and has realized the necessity of taking care of the body. Since writing the above N. G. has been appointed to an associate professorship.

Case IV.—R. This man does not belong, clinically, to the group we have been studying, but he must be included in the group from a sociological and occupation viewpoint. He is a well known Romance scholar and has done some remarkable work. He is married, and is 41 years old. He worked for his Ph.D. at the Johns Hopkins some years ago, but secured a position in a large western university before taking his degree. While at this university he became somewhat erratic, suspicious of his wife and friends, and finally an attack of dipsomania caused his friends to send him to a sanatorium to cure him of the "drink habit." It was not recognized at the time that dipsomania is a psychic epileptic equivalent, and he was told if he ever drank again he would lose his position. Six months in the sanatorium benefited him physically, but undoubtedly, judging from the events which followed, there was a constant deterioration of cortical activity. A few weeks after his return to his home and university work he disappeared. He was found in a distant town where he was an ambulant visitor to all the saloons and without any clear recognition of the real ego. He was arrested and confined in jail for several days, then dismissed from the university, and advised and assisted to return to Baltimore to resume his postgraduate studies. The excuse for such advice is that he was dangerous at home, and it was thought that the surroundings in Baltimore might aid him in controlling the "drink habit." Certainly this was odd reasoning to apply to a man who was fast showing a morbid personality and some phenomena of degeneration. These stigmata of a degeneration became more prominent as he remained in Baltimore, and it was deemed advisable to send him to a sanatorium. He remained there for a few weeks, but became so careless in his speech and habits that he could not be tolerated. He has disappeared, and belongs to that unfortunate class whose members "drop out of sight."*

New York, July 1, 1905.

## THE POLITICAL POWER OF THE PHYSICIAN.

On the occasion of the graduation exercises of the United States Naval Medical School, held at the Naval Museum of Hygiene, in Washington, on March 25, President Roosevelt delivered the diplomas to the graduates and made an address upon the duties and the opportunities of the naval medical officer. The address dealt in general with the dual character of the graduates as medical men and officers of the navy, and with the opportunities presented to them of studying rare forms of disease, especially diseases peculiar to the tropics or the modification in type of ordinary diseases as met with in hot climates.

But the point of special interest upon which the President dwelt at some length was the need of an increase in the medical service both of the army and of the navy. Every effort, he said, should be made to provide the surgeon with ample means to do his work. "Every effort ought to be made to persuade the National Legislature to take that view of the situation; to remember that in case of war it is out of the question to improvise a great medical service for the army and navy. The needed increase is more keenly felt in the army than in the navy, because it is always the army that undergoes the greatest expansion. But it is felt in both services. If a war come for which we have no greater preparation than at present we have made, if, as is perfectly certain to be the case, there be fever in the camps; if there be trouble among the volunteer forces, it is foolish to the greatest degree for the public men, and especially for the public press, to complain and shriek over the people who happen to be in power at that time. Let them shriek—or rather do not let them shriek at all, for shrieking is a sign of hysteria—but let them solemnly think over and repent of the fact that they have not made their representatives provide adequately in advance for the medical system in its personnel, its material, its organization and physical instruments necessary to make that organization effective, which alone, if prepared in advance, will obviate the trouble which otherwise is certain to come if we have a war. Let them remember not to blame the people in power when the breakdown comes, but blame themselves—the people of the United States—because they have not had the forethought to take the steps in advance which will prevent that breakdown occurring."

As regards the need of better preparation for a possible emergency, the President spoke well, but it was rather startling to have him put the blame for failure on the people. The people cannot pass laws, or vote appropriations, or reorganize the public services. These are the prerogatives of Congress. It is true the people elect the Congressmen, and if the Congressmen do not do their will they can defeat them at the next election, and put in the candidates of the opposite party. But Congressmen are elected for a long term, and there are many other questions of moment to be determined during a session of Congress—some of them of more vital importance to the welfare of the nation than even the personnel of the medical services. The nation would be happy indeed, if all questions of policy, foreign and domestic, were so adjusted that an issue at the polls could be made solely on matters relating to hygiene and the public medical services—but that would be Utopia.

Nevertheless, the President is right. Although the medical profession of the country will probably never be able to influence national legislation or health matters by minatory measures, it can accomplish much through personal influence. Every physician in the United States knows, or ought to know, who is his representative in Congress. If there happened to be a bill before the National Legislature affecting him personally, he would lose no time in seeing or writing to his representative urging its passage or its defeat as the case might be. Then let him make this a personal matter. If each and every physician would take an individual interest in this measure, and write to the Representative in Congress from his district, and to the Senator from his State, urging the passage of a bill to improve the medical services of the army and navy, it would not be long before a great light was seen in the Capitol. Importunity is the weapon of the minority, such as is the medical profession in politics. One hundred thousand letters addressed to the members of Congress would be far more effective than one hundred thousand scratched tickets at the polls.

It will be a long time before Congress meets again, but good resolutions are sometimes strengthened by incubation. Summer is a good time for thought. If every physician, during his period of leisure, will ponder over the duty he owes to his country and his profession, and over the power for good that resides in him as an individual; if he will follow the proceedings of Congress next winter, and when a bill to improve the medical services is introduced, as it will be, will seize the opportunity to urge its passage upon his Representative and his Senators, the result will be an object lesson to the medical profession, and will open the eyes of its members to the fact that they have real power, not only in this but in all matters relating to public health. A minister of public health should have a seat in the Cabinet of the President. He will never be put there by resolutions of delegates to the American Medical Association, but he can be put there by concerted individual effort of the medical men of the country.

## AN INTERESTING LESSON IN EPIDEMIOLOGY.

To find the cause of a disease is often difficult, sometimes interesting, and always important. In the May number of the *Journal of the Royal Army Medical Corps* is an article by Major Cathcart Garner, which shows in a striking way the various difficulties and disappointments that have to be encountered in the search for the cause of an epidemic, and also demon-

strates the absolute necessity of undertaking such investigation with a mind entirely free from prejudice. From the article in question we learn that early in September it was reported that in the village of Seyaffa, in Egypt, plague (probably pneumonic) had appeared, and that the normal death rate for the month had already been exceeded. Such news was particularly surprising at that time of year, and subsequent investigation into the cause of the increased rate of mortality led to interesting discoveries. First of all, the laboratory reports negatived the diagnosis of plague. Next the clinical findings in the hospital were also against the diagnosis of plague. All the sufferers were women, all were over thirty-five years of age, no two cases had occurred in the same or adjoining houses, most of the deaths had occurred within thirty-six hours from the commencement of the attack, the patients had all complained of intense pain over the sternum, and all retained consciousness till the end. A few days after these first observations, a woman was found suffering from malignant pustule, and two days later a man was found with anthrax; and cultures taken from persons dying within that same week all showed pulmonary anthrax. The diagnosis being settled, the question now arose as to its origin and mode of infection. The possibility of cattle, hides, or wool being the starting point was eliminated by the very careful trade restrictions, disinfection, and burning of refuse which had been enforced in the district on the first appearance of the disease and on the supposition that it was plague. A diligent search among the sheep within a radius of twenty miles of the village was also negative in its results. Had an infected carcass polluted the water, and the women (who are the water-carriers in the community) in this way become infected? Careful inquiry along this line proved of no more value than the previous ones. A dead donkey was at last the means of starting the investigators on the right track. It was found that there had been an abnormally great mortality among the donkeys, as well as among the women. Further investigation showed that these donkeys had died of pulmonary anthrax, and also that the human and the asinine cases had both occurred in adjoining houses and courtyards. But how had the donkeys become infected, and what relation did their infection bear to that of the women? The article in question shows that "a small outbreak of anthrax had occurred amongst cattle and sheep at the time when attention was centered on rinderpest; and the cases of anthrax having escaped notice had been returned as cattle plague. The droppings of these animals infected with anthrax had been collected and made into gilla (a cake made of dung and chopped straw, and used for fuel), which subsequently infected both women and donkeys. The mode of infection in both had been similar, namely, by inhalation; the donkey snuffing at the gilla heap, the woman inspiring gilla dust when baking.

## Schiller as a Medical Man.

The interest evoked by the recent centenary commemoration of Schiller's death, on May 9, 1805, has been widespread in this country as well as in Europe, yet but little attention has been paid to the fact that Schiller, like Rabelais, Smollett, Sir Thomas Browne, and others now best known for their achievements in letters, was originally a practising physician and surgeon, who expected to make medicine his life-work. The son of a forester and a baker's daughter, his first inclination was toward the study of theology. This ambition gave way to the necessity for adopting a more remunerative vocation, and for a time he devoted himself to jurisprudence, but later abandoned this career, in turn, in favor of the medical profession. His imaginative temperament was early evident, however, and his first dissertation on "The Philosophy of Physiology" was so daring a revolt against tenets of the day and particularly the dicta of their universally adored Haller, that his examiners confessed themselves unable to follow his reasoning and regarded the work as too unsafe to be printed. Even the young candidate's patron, Duke Charles of Würtemberg, to whom the question was submitted, was of the opinion that another year's sojourn in the academy would be of benefit to him; in short, he was "plucked." The next year he submitted two essays, one on the nature of fevers, which again was too radical for the spirit of the times and failed to gain professional approbation, while the other, a purely philosophical work entitled "Observations on the Relationship Between the Animal and Spiritual Nature of Man," was accepted. In some way, however, Schiller had lost the favor of his ducal protector, who, with characteristic fickleness, instead of the promised sinecure bestowed on him only the post of assistant surgeon to an ill-famed tatterdemalion regiment of grenadiers, without officer's rank or the right to wear a sword, and at the pay of only 18 gulden a month. His career in this position was not particularly fortunate; the disciplinary restrictions were very irksome and the artistic temperament manifested itself in what were, for those days at least, strange experiments with his patients, and his propensity for prescribing drastic or incompatible doses finally became so notorious that by a special regulation each of his prescriptions had to be submitted to his superior before being filled. One scrape followed another, his budding literary fame was frowned upon, and he was forbidden to publish any writings on other than medical subjects; and, finally, after he had been ordered fourteen days' imprisonment for having attended the first two performances of his drama, "The Robbers," without leave of absence, he made his escape from his distasteful surroundings. Before this decisive step, his ambition had been to reach a professorial chair in physiology, but after leaving the regiment he did little further work in medicine, and the world had lost an obscure military surgeon, but had gained an illustrious poet. Still, as in Goethe's case, the early scientific training left a lasting impress on his work, and it is not difficult for the medical reader to detect in Schiller's later writings many traces of his early habit of mind.

## Unauthorized Surgical Operations.

The point as to whether a surgeon is justified in performing an operation without the consent of his patient, even if in the opinion of the surgeon the best results will follow, is a delicate one. The operator may argue that his skilled knowledge should render him the best judge of the situation and that consequently he should be given a free hand. This view of the question is intensified when the patient's mental condition is such that he is hardly fitted to regard the matter from a sane standpoint. A case of unauthorized operation has been decided recently by the Appellate Court of Illinois, and is referred to in *Case and Comment* for March, 1905. A woman entered a hospital for some slight operation, and afterwards returned and submitted, as she supposed, to another of the same character. The surgeon, however, performed a major operation, and subsequently the woman brought an action against him for performing the operation without her consent. The defence of the medical man was that he deemed that "her mental condition was such that it was

impossible to take her into advisement on her own case." The judgment of the Court was that "except in cases where the consent of the patient is expressed, or is implied by circumstances and occasions other than a more general retainer for medical examination and treatment, and except, also, where there is superior authority which can legally and rightfully dispose of the person of the patient, and which gives consent, a surgeon has no right to violate the person of the patient by a serious major operation, or one removing an important part of the body." On the whole, it may be said that this judgment is a fair one. As to whether the surgeon should not be the best judge with regard to the nature or scope of an operation is another matter. However, an individual should have the right to determine the question of an operation upon himself, albeit such a course may be against his best interests. The case here mentioned is interesting from the fact that the judicial decision given with regard to it is said to be first respecting a surgeon's liability for performing an unauthorized operation.

### Radium Creation of Life.

Much interest has been aroused among newspaper readers—the term embraces us all—by a statement that Mr. John Butler Burke, of the Cavendish Laboratory, Cambridge, has "almost certainly" demonstrated the possibility of the creation of life where none existed before. According to the cabled report, Mr. Burke submitted some sterilized bouillon in a test tube to the action of radium and, after a time, discovered in the bouillon a number of minute round objects about 1 micron in diameter. These he was tempted to regard as living objects, though on what grounds the cable does not inform us, but Prof. Sims Woodhead, who examined them, is said to have pronounced them crystals, since they were soluble in water and incapable of reproduction. For want of a better name, the discoverer gave them the very poor one, since it implies that they are living organisms, of radiobes. One would be rash to deny the possibility of life appearing *de novo* upon this planet, or any other, but that it has been created in this instance we see no proof. It is far more likely that the phenomenon was of a similar nature to that previously observed by Mr. Soddy, who detected certain microscopic particles in the glass of a tube in which radium had been contained. Prof. Loeb, who was credited recently with creating life because he hastened the process of parthenogenesis in the eggs of the sea urchin, apparently was nearer to it than Mr. Burke; but he was no nearer to it than any farmer who hastens the germination of his seed by watering and manuring. The discovery of the principle of life in the near future need surprise no one who has kept himself informed of the wonders revealed by a study of radioactivity, but the discovery of the riddle of life will not necessarily give us the power to create it.

### The Physician's Bills.

That the physician is generally the last man to be paid is a notorious fact. It is also almost as well-known that the medical man, as a rule, is lax in business matters. Another somewhat curious point is that many rich people have no scruples in obtaining a doctor's services at the least possible cost. Such persons may be regarded in the ordinary affairs of life as just and equitable and would never dream of attempting to swindle their butcher or baker, but where the doctor is concerned they will resort to all kinds of low methods, with consequent loss of self-respect, in order to have the use of his skill for a paltry sum. The *New York Tribune* of June 18 contains an article dealing with the difficulties which physicians meet when they come to collect their bills. The writers gives numerous instances of the unwillingness of persons to discharge their debts to the doctor, and of their willingness to obtain his services for little or nothing. As a matter of fact, the inability of physicians to collect their just dues is to a great extent their own fault. It is because of lack of business methods. To be in these days a successful physician, financially, one must also be a good business man, and must be as insistent in claiming payment for work done as is the merchant in recovering the amount due for goods sold and delivered.

## News of the Week.

**Plague at Panama.**—A death from what is supposed to have been bubonic plague is reported to have occurred at La Boca, three miles from Panama, on Friday of last week. The dead man, a laborer, had been working on board the British steamer *Chili*, which the authorities of Guayaquil would not allow to enter that port. The house in which the man lived was thoroughly disinfected, and his forty companions were isolated and kept under observation. Rats taken from the steamship are to be examined at Ancon. Three sailors had died on the ship during her voyage from Iquique, Chile, from what was suspected to be the plague.

**Yellow Fever on the Isthmus.**—A number of new cases of yellow fever have been reported from Panama, Colon, and intermediate points in the canal zone during the past week. The Canal Commission has decided to build new hospitals, one at Empire with 500 beds, one at Colon with 96 beds, and one at Taboga with 100 beds, and also to build a sanatorium. The Commission will also take charge of the hospitals at Panama, which will be rebuilt and equipped with modern accommodations and appliances.

**The Cornell Commencement.**—At the seventh annual commencement of the Medical Department of Cornell University, last week, 74 students were graduated, of whom 62 received hospital appointments. The annual prize established in memory of John Metcalf Polk, to be presented at graduation to the three students who have obtained the highest marks for the four years of their work in the college, was awarded to Rollin Hills, Milton Goodman Wasch, and Otto Louis Goehle. The exercises were held in the college building in the afternoon, and the address to the graduates was delivered by Dr. George H. Simmons, secretary of the American Medical Association and editor of its journal. Following this was a reception to the friends of the college given by the president of the university and the faculty of the college. In the evening the Medical Alumni gave a banquet to the graduating class. Dr. Polk, Dr. Simmons, and the president of the class, Dr. Mallon, responded to toasts.

**Pennsylvania State Department of Health.**—Dr. Samuel G. Dixon, the new Commissioner of Health, has appointed Dr. Benjamin Lee of Philadelphia Assistant Commissioner, and Dr. Frederick C. Johnson of Bradford Chief of the Division of Inspection, Quarantine, and Disinfection. Dr. Lee was for twenty years secretary of the Pennsylvania State Board of Health, and Dr. Johnson was formerly resident physician in the Philadelphia and Municipal hospitals.

**Famous Witch Doctor Dead.**—"Dr." Joseph H. Hagemann died at Reading, Pa., on June 19, at the age of 73 years. He was a famous witch doctor, whose charms and incantations were sought for sickly infants and ailing farm animals alike. He enjoyed an immense practice and was one of the celebrities of his neighborhood. He dealt in charms calculated to cure the diseases of both man and beast.

**The Death Rate in Philadelphia** has undergone an increase coincident with the extreme hot weather. The number of deaths for the week ended June 24 was 451, as compard with 421 for the preceding week, and with 395 for the corresponding week of the previous year. One hundred and thirty-two of the deaths occurred in children under the age of 1 year, and 23 in individuals between 80 and 90 years of age.

**Typhoid Fever in Philadelphia.**—One hundred and sixty-four new cases of typhoid fever, with 14 deaths, were reported to the Philadelphia Bureau of Health for the week ended June 24, as compared with 166 cases for the preceding week. About three-quarters of the cases occurred in sections of the city receiving unfiltered water from the Delaware River by direct pumpage.

**New Health Commissioner of Chicago.**—Mayor Dunne has appointed Dr. Charles J. Whalen as Commissioner of Health of Chicago, to succeed Dr. Arthur R. Reynolds, who has held the position for eight years. Dr. Reynolds has been a most efficient health officer, and hundreds, if not thousands, of the inhabitants of Chicago at the present day owe their lives to him and to the assistants inspired by his sanitary zeal.

**Military Surgeons of Illinois.**—At the annual meeting of the Association of Military Surgeons of the State of Illinois, held at Danville, June 8, Dr. Nicholas Senn was re-elected president, and Dr. Charles Adams, secretary. Among the papers read at this meeting were one by Dr. Charles D. Center of Quincy, entitled "Influenza," and another on the "Mastoid Operation" by Dr. George P. Marquis of Chicago. Dr. Senn spoke on the subject of iodine and its use as a bactericide. Dr. S. C. Stanton of Chicago demonstrated the method of physical examination of recruits.

**Annual Meeting of the Chicago Medical Society.**—This society held its annual meeting June 21, when Dr. Chas. S. Bacon was elected president, and Dr. Frank X. Walls secretary. Reports of officers of the various branch societies, as well as the affiliated societies were presented, showing that the society was in a flourishing condition, with a membership of 1,710.

**Trouble Over Bellevue Hospital Food.**—The house staff, clerks, and orderlies of Bellevue Hospital have been in open revolt against what they allege is the poor quality and insufficient quantity of the food provided for them, and have complained in writing to the hospital authorities. Owing to lack of seating capacity, the orderlies are obliged to take their meals in two detachments, and it is said that those in the second section usually find but short commons awaiting them. The dietician of the hospital has sent in her resignation.

**A Woman Professor of Johns Hopkins.**—Dr. Florence R. Sabin has been appointed associate professor of anatomy in Johns Hopkins University. She is a graduate of Smith College and of the Johns Hopkins Medical School.

**Illegal Licenses to Practice in Oklahoma.**—Owing to a change in the regulations concerning the practice of medicine, trouble has arisen over a large number of licenses recently granted in Oklahoma. Prior to March 12, 1903, graduates of recognized colleges of medicine were granted licenses to practice in Oklahoma upon the presentation of their diplomas and the payment of a fee of $2. Since that time licenses have been granted only upon examination. During the interval of nineteen days between the time the new law became effective and the time when the new Board of Health was organized 180 licenses were issued to applicants. P. C. Simons, the territorial attorney general, holds that the old law was not operative when these licenses were granted and that they are illegal. It is alleged that circular letters were sent to different medical colleges advising them that they should take advantage of the opportunity of having their graduates licensed to practise before the new law was in force. The 180 physicians will be required to take the regular medical examination or discontinue their practice in Oklahoma.

**Memorial to Dr. E. A. de Schweinitz.**—The faculty and students of the Medical and Dental Departments of the George Washington University have erected, in the main hall of the medical college, a beautiful bronze tablet to the memory of Dr. E. A. de Schweinitz, who at the time of his death was dean and professor of chemistry in that institution. The memorial is 2 by 3 feet in size, with an appropriate inscription.

**Dr. John C. Hemmeter** of Baltimore received the honorary degree of LL.D. from St. John's College, Annapolis, at the commencement held June 21.

**Dr. Joseph E. Fuld** has been appointed adjunct surgeon to the Sydenham Hospital.

**Dr. William S. Bainbridge** has been appointed consulting gynecologist to St. Mary's Hospital, Jamaica, L. I.

**Examination for Laboratory Assistant.** — The Municipal Civil Service Commission of New York will hold an examination on July 12 at 10 A. M. to fill a position of laboratory assistant in the Department of Health. The applications will close on July 5.

**Unable to Starve, so Starved.**—Frau Liza Schenk, a professional faster in Hamburg recently committed suicide by hanging because she was starving owing to her failure to get fasting engagements.

**International Tuberculosis Association.**—At a meeting of the executive committee of the International Tuberculosis Association, held at the Ministry of Education, in Berlin, on Thursday of last week, application for membership was received and accepted from the American National Association for the Study and Prevention of Tuberculosis. This is the twenty-first national society to join the international association.

**Prize Essay on Sabbath Observance.**—The Woman's National Sabbath Alliance offers a prize of $25 for an essay of not more than 2,500 words, demonstrating the urgent need of a weekly mental and physical rest-day. "The experience of a Christian physician is preferred." Manuscripts, with the name and address of the writers in a sealed envelope, will be received until the 1st of November next, at the headquarters of the Alliance, Room 709, 156 Fifth avenue, New York City. The accepted manuscript shall become the property of the Alliance, and the others will be returned when called for or accompanied by the full amount of postage needed.

**A New Hospital in Orange.**—The first ward in the new Italian Roman Catholic Hospital in Orange, N. J., was opened the middle of June. It is called the ward of St. Anthony. The hospital itself is called

the Hospital of the Immaculate Conception. It occupies four separate buildings on Centre and Hurlbut streets.

**A Lectureship on Tuberculosis.**—The State University of Iowa has established a lectureship on tuberculosis in connection with the medical department of that institution, and has appointed Dr. J. W. Kime, of Fort Dodge, as lecturer.

**Excursion to Lisbon.**—Arrangements are said to have been completed for the chartering of a vessel to carry American members of the fifteenth International Medical Congress to Europe. Opportunity will be given the excursionists to visit a number of interesting points in Spain. The round trip will cost from $275 upward. Further information can be obtained from Dr. Charles W. Fassett, St. Joseph, Mo.

**Prices of Patent Medicines Raised.**—In an effort to stop the universal cutting of prices of proprietary remedies, the manufacturers of practically all the best known preparations have united in compelling retail druggists to sign ironclad contracts not to sell the goods in question at less than a rate fixed much higher than those which have been prevailing. This action has been taken with the cooperation and approval of the National Retail Druggists' Association, the members of which it is designed to protect, by taking the traffic in patent medicines out of the hands of the department stores.

**The Benefits of Registration Laws.**—The people of California are beginning to appreciate the fact that the medical laws are intended for their protection, and quite a number of prosecutions have been brought against charlatans within the last few months. Other cases have been brought by the local medical societies, and the life of the quack is no longer a happy one. The fines assessed in cases of conviction range from $100 to $250.

**Photographs of Applicants Required by Colorado State Medical Examiners.**—In order to lessen the fraud that has been practised in Colorado in regard to the state licenses to practice medicine, the State Board of Medical Examiners has made a regulation to the effect that each applicant must file with the board two photographs of himself, together with two affidavits as to his moral character signed by reputable physicians. After July 1, every applicant must submit to examination, no matter from what school he was graduated.

**Minnesota State Medical Association.**—At the recent meeting held in St. Paul, the following officers were elected: *President,* Dr. C. H. Mayo of Rochester; *First Vice-President,* Dr. D. W. Jones of Gaylord; *Second Vice-President,* Dr. Theo. Bradrud of Warren; *Third Vice-President,* Dr. S. H. Boyer of Duluth; *Secretary,* Dr. Thomas McDavitt of St. Paul; *Treasurer,* Dr. R. J. Hill of Minneapolis.

**The Middle Tennessee Medical Association** adjourned its annual session held in Franklin, after the election of the following officers: *President,* Dr. L. E. Burch of Nashville; *Vice-President,* Dr. C. N. Cowden of Fayetteville; *Secretary and Treasurer,* Dr. Wm. Litterer of Nashville. The next meeting will be held at Lebanon.

**Sioux Valley Medical Association.**—At the close of the meeting of this society, held at Fort Dodge, Ia., the following officers were elected: *President,* Dr. C. H. Churchill, Fort Dodge; *Vice-President,* Dr. A. E. Cook, Randolph, Neb.; *Second Vice-President,* Dr. R. E. Woodworth, Sioux Falls, S. D.: *Treasurer,* Dr. S. A. Brown, Sioux Falls, S. D.: *Secretary,* Dr. F. E. Franchere, Sioux City, Ia.

**Northern Tri-State Medical Society.**—The following officers were elected at the session of this society, held at Fort Wayne, Ind.: *President,* Dr. W. J. Gillette, Toledo; *Vice-President,* Dr. Theodore Wood, Angola, Ind.; *Secretary,* Dr. W. Schumaker, Butler, Ind.; *Treasurer,* Dr. A. G. Holbrook, Coldwater, Mich. The next meeting will be held in Detroit in January, 1906.

**Massachusetts Medical Society.**—At the annual meeting of this society, held in Boston, the following officers were elected: *President,* Dr. A. T. Cabot of Boston; *Vice-President,* Dr. F. H. Thompson of Fitchburg; *Corresponding Secretary,* Dr. Francis W. Goss of Roxbury; *Recording Secretary,* Dr. Edward H. Brigham of Brookline; *Treasurer,* Dr. E. M. Buckinham of Boston.

**The Death Rate in New York City** for the week ending June 24 was 17.20 per 1,000, as against 22.98 for the corresponding week of last year. The large number of deaths last year was due to the *Slocum* disaster, in which many children on a church picnic were burned or drowned. The deaths for the week from cerebrospinal meningitis numbered 34; in the week ending June 23, 1904, there were 51 deaths from this disease.

**Obituary Notes.**—Dr. Francis Drummond Gilbert died in San Francisco on May 31, at the age of 85 years. He was born in England and received his medical education in London. He lived for some time in Canada, going to San Francisco in 1873, where he practised until 1897.

Dr. Edwin D. Simpson died in this city on June 23 of disease of the heart, at the age of 52 years. He was born in this city, and was a graduate of the College of Physicians and Surgeons in the class of 1874. At the time of his death he occupied the chair of suggestive therapeutics in the New York Homeopathic Medical School.

Dr. George Philip Fenwick of Washington, D. C., died June 15, at the age of 67 years. He was born in Oak Grove, D. C., and was graduated in medicine at the Columbian University of Washington March 3, 1859. He served on the Board of Health from 1861 to 1871; was a member of the Medical Society of the District of Columbia; a member of the Obstetrical and Gynecological Society, and a member of the Medical Association of the District of Columbia.

Dr. William F. Reus of Grand Haven, Mich., died June 14, at the age of 83 years. He was born in Holland and when a young man served in the Netherlands navy, being stationed in the Dutch Indies. Coming to America, he served under Farragut in the war. Dr. Reus had practised his profession in Grand Haven thirty years, having a large clientele among the Dutch residents.

Dr. Thomas B. Gunn of North Yakima, Wash., died June 14, from intestinal obstruction, at the age of 59 years. He was a graduate of the Missouri Medical College, St. Louis, in the class of 1874. He had practised in North Yakima about fifteen years.

Dr. Walter Bryan of this city was found dead in his office on June 26. He was 38 years of age, and was a graduate of the New York University Medical School in the class of 1890. He was one of the faculty of the Brooklyn College of Pharmacy and had been professor of natural history in the College of the City of New York. He was a member of the American Association for the Advancement of Science.

Dr. Franklin B. Maner of Itaska, Tex., was shot and killed in a street duel on June 26. He was a graduate of the Medical Department of Vanderbilt University, Nashville, in the class of 1880.

# Correspondence.

## THE AMERICAN MEDICAL ASSOCIATION; WAS IT REORGANIZED ON CORRECT PRINCIPLES, AND WILL IT, UNDER METHODS PURSUED, ACCOMPLISH WHAT IT OTHERWISE MIGHT?

To the Editor of the Medical Record:

Sir: Some of the "sins of commission" in the alleged constitution of the American Medical Association, were commented on in the last communication, but those of "omission" were left untouched, being so numerous it was impracticable to undertake to deal with them.

A brief review of the By-laws and methods of procedure of the American Medical Association will complete this discussion.

By reference to any one of the four editions of the "New Constitution," it will be observed that the Constitution is short and the By-Laws long, the proportion in the last edition being as 2:12. This large disproportion is significant, and at once arouses a suspicion that the By-laws must contain much that properly belongs to the Constitution. When one begins to read, this suspicion soon deepens into conviction. The well-known rule that governs in such matters is definite and just, that is, principles and important details must be embodied in the Constitution, whilst matters of quite secondary importance are to be provided for in the by-laws. A hasty glance at the By-laws under discussion will show how grossly this rule is violated.

Chapter I deals with the question of "membership," how obtained, who shall be eligible, etc. Is that not a most fundamental and important subject? Does it not lie at the very foundation of the entire system of organization? If so, and of this there can be no doubt, then it emphatically belongs to the Constitution. Aside from being misplaced, this chapter contains some radically wrong and thoroughly untenable provisions. Think of conceding to the "general secretary," as this chapter does, or for that matter to any other officer, the right of admitting and expelling members upon ill-defined conditions and upon information that might sometimes be inaccurate. For a corporation to abdicate two of its highest and most important functions and confer them upon one person is simply monstrous and unprecedented! To render the case, in this instance, infinitely worse, the "general secretary," upon whom such supreme authority is conferred, need not be, and as a matter of fact is not, himself even a member of the House of Delegates. The most elementary thinker on the subject of constitutional provisions would in formulating a constitution have restricted the right of the "general secretary" to receiving applications for membership and reporting them to the Association for such action as it might see fit to take thereon. To forestall possible objection to this proposition on the ground that it would be impracticable, the writer will say that did time and space permit it would be easy to point out a way in which the admission of members could be very expeditiously attended to by the Association itself. So far as expelling members is concerned, or dropping them from membership, that is a function that should not be exercised by the Association except in accordance with a prescribed and systematic investigation, to outline which would require more time than is now at disposal. If the Association itself should exercise great care in dropping the name of a member from its rolls, then how unjust and unwise to permit the "general secretary" to do it upon very inadequately defined grounds.

The subjects of which Chapter II of the By-Laws treat also belong to the constitution and should have been included therein.

The three first sections of Chapter III, providing for dental and pharmaceutical members, should have no place in either the By-laws or Constitution. Dentists and pharmacists have their own national organizations and should concentrate their support on them, and not divide it with other national organizations. For the same reason, it would not be wise for the national dental and pharmaceutical associations to admit physicians to regular and active membership. Whilst courtesies between the American Medical Association and the bodies named would be entirely proper, interchange of membership is unwise and impolitic, and is not conducive to the best interests of any of the organizations concerned. Further, a suspicion will insinuate itself into one's mind that the motive back of these provisions of the By-laws is a mercenary one. If so, that would condemn them forever.

The three last sections in this chapter deal with Associate and Honorary Members and Members from Adjoining Countries. The provisions in regard to such members are unnecessarily mixed and confused, and yet are susceptible of easy solution. Honorary members, for instance, are provided for in three separate places, instead of being disposed of at one place.

The subjects treated in Chapters IV, VI, VII, and VIII of the by-laws conspicuously belong to the constitution and should be transferred there. Whilst objection might be made to a number of provisions in these chapters, they will be passed by for the present, with the right reserved, however, of referring to them should occasion arise.

Chapter IX is devoted to the Board of Trustees, and inasmuch as the Articles of Incorporation vest the management of the Association in a board of nine trustees, the discussion of this chapter is important. Logically, this chapter, or rather the subject of which it treats, belongs to the Constitution, but doubtless the framers of that instrument would endeavor to defend their action in placing it in the By-laws by pointing to the Articles of Incorporation, in which the following words occur: "Trustees . . . are to be elected as the By-laws direct." Obviously, it is only the provision regulating the way in which the trustees are to be *elected* that must appear in the By-laws; all else referring to this board might and should have appeared in the constitution. The writer is under the impression that information has reached him to the effect that Illinois statutes (under which incorporation was obtained) confer upon corporations the right of amending their Constitutions and By-laws at any annual meeting. If so, this might be urged as a reason for putting so little in the Constitution and so much in the By-laws. But, accepting the fact, defence does not necessarily follow. Rather than violate a fundamental and authoritative rule in regard to the construction of Constitutions and By-laws, it would have been better to put in the Constitution what naturally and logically belongs there, and then conform to Illinois law by providing that the Consitution could be amended at any annual meeting, than to insert in the By-laws matter that obviously and palpably does not belong there.

Before proceeding, however, with the discussion of this chapter, it is worth while to point out the stupendous absurdity of vesting the management of the Association in a Board of Trustees. In law, trustees are provided for the management of the estates of minors, of people who are *non compos mentis*, or of people who for any other cause are incapable of managing their own affairs. Does the American Medical Association belong to either one of the categories? If not, then, it should as soon as possible be released from the humiliation which the present articles of incorporation impose upon it.

The first clause in the chapter under discussion is a broad and unqualified mandate, as follows: "The Board of Trustees shall have charge of all properties and of the financial affairs of the Association." If this clause is to be literally construed, then, the rights of the Association in so far as the management of its affairs is concerned consist in electing trustees, that, and nothing more. If the clause is not to be literally construed, then, what does it mean, what qualifications shall be applied to it? If the Constitution itself does not explain, who can? Is not a wide gap left here for wrangling and differences of opinion? Is it artistic in "constitution building" to leave such room for doubts, uncertainties, and disputes? Did the framers of the Constitution ever stop to think closely and logically upon the exact scope and meaning of their words? Have any of the larger committees to which the several editions of the "New Constitution" were referred ever given the document anything more than a hasty and superficial reading? If not, is it a matter of surprise that crudity and indefiniteness have resulted? Passing over the third and fourth clauses in the chapter, both of which are open to criticism, the fifth clause reads as follows: "It [the Board of Trustees] shall appoint a general manager and editor of The Journal, which two positions may be held by one person, and such assistants as may be necessary, and shall determine their salaries and the terms and conditions of their employment."

If this is not imperialistic of the highest type, the writer would acknowledge his profound obligations to any one who will furnish a better example of that kind of authority. Not so much as, "by your leave," or "with your approval." That is, the Board of Trustees must do all!

The next clause reads as follows: "All resolutions or recommendations of the House of Delegates pertaining to the expenditure of money must be approved by the Board of Trustees before the same shall become effective." Possibly the legal status of the Board of Trustees, as fixed by the Articles of Incorporation, may justify the unprecedented requirement laid down in the above provision, namely, that acts of the Association must be approved by one of its creatures, but, if the legal status be so, the first effort at reorganization should have been to appeal to the State of Illinois so to amend the articles of incorporation as to enable the Association to outrank in authority any one of its own agents or creatures.

Passing over a number of clauses, the following one is

reached: "The Board of Trustees shall fix the salary of the secretary and treasurer." Here, again, the Board is crowned with imperial authority, and is not even required to consult with, or ask the approval of, the Association in reference to an important matter. The Association must, according to the constitution, *elect* a secretary and a treasurer, but according to the by-laws can have no voice whatever in fixing the salaries of these officers! It was seen above that the Board of Trustees "shall appoint a general manager and editor of The Journal" and fix his salary. We now see that the same board must fix the salary of the secretary. The very pertinent question arises: When all three positions are filled by the same person, how many salaries are fixed? In this connection it is not out of place to look into one of the annual reports of the Board of Trustees and see what may be found. The one submitted last year (1904) will be used. It seems from this report that the revenues of the Association for 1903 amounted in round numbers to two hundred and twenty-five thousand dollars. They must be considerably greater than that now. It is evident, therefore, that the management of the finances of the Association has grown to be a stupendous responsibility. Without stopping to analyze the figures of the report, although they stand in obvious need of explanation, attention will be called to the following quotation from the report: "Just at this point we desire to call attention to the fact that your Treasurer's Report differs from those of former years from the fact that since March 1, 1903, he has been really the Treasurer of the Association, receiving from The Journal office only the surplus funds of the Association, not collecting the dues as formerly. All dues are now collected in The Journal office, through the bookkeeper. This change in methods of bookkeeping has resulted in simplifying accounts and has curtailed the expenditures of the Association materially, having completely done away with the necessity of transferring monies from The Journal office, to be within a few days drawn out again from the treasurer and used in The Journal office. Now The Journal collects all accounts, whether dues, subscriptions, or advertisements, or whatever else they may be, uses the money in paying all expenses of The Journal and the Association, and hands over the surplus to the Treasurer. He becomes the custodian of the funds of the Association that are not in active use, and of the invested funds."

As a piece of financial philosophy the position here advanced is certainly one of the most fallacious on record. According to the reasoning submitted, if a corporation had no surplus it would not need a treasurer at all, although millions of dollars might pass across its desk annually. The proposition that the treasurer of a corporation is only really the treasurer when he merely handles the surplus and the invested funds is certainly unique and original.

We are told in the above quotation that the bookkeeper in The Journal office "collects all accounts, whether dues, subscriptions, or advertisements or whatever else they may be, uses the money in paying all expenses of The Journal and the Association, and hands over the surplus to the Treasurer." With the revenues of the Association amounting to more than two hundred thousand dollars, passing through the hands of that bookkeeper, it would be interesting to know whether he is required to give bond? Formerly, the treasurer was required to give bond, and as he has largely become a "figure-head," it would seem right and proper that whoever handles the revenues of the Association in The Journal office should be required to give an adequate bond.

Another point in connection with the Report of the Board of Trustees: The board states that it has had the accounts covering the financial operations of the Association audited by a professional auditor. As the board reports to the Association, would it not be much more logical for the Association to appoint a committee to audit the financial report of the Board. Would the following not be a strictly parallel position to that taken by the Board of Trustees in reference to auditing the accounts of the Association: The treasurer of a large corporation in submitting its annual report informs the Directors that he has had his accounts audited by a professional auditor, consequently nothing further in the way of auditing will be needed. Would the Directors be likely to accept such auditing? The writer distinctly disclaims any intention of discrediting the correctness of the accounts, he is simply calling attention to the business principles involved.

Chapter X of the By-laws is devoted to "Committees," and contains many curiosities The first one of these appears in section 1, and consists of classifying the committees before provision is made for their creation, which is certainly reversing the natural and logical order of things.

Another curiosity also appears in this same section, as may be seen by the following provision: "These Committees shall be nominated by the President and elected by the House of Delegates, unless otherwise provided." Comment is unnecessary in order to point out several incongruities in this provision, one of the most obvious of which is: How one and the same committee is to be nominated by the President and elected by the House of Delegates? Suppose the President should nominate certain persons as members of a committee and the House of Delegates should elect others, what would be the status? The President of the United States is required to nominate some officers and the Senate to confirm. In case of a conflict the status is clear, but in the case under discussion it is far from clear.

The section in this chapter providing for a "Committee on Medical Legislation" would richly reward a hunter after "curios." The second sentence reads as follows: "This Committee shall have power to cooperate with the officers of the State and local societies, and with the chief officers of the U. S. Army and of the Navy, and of the U. S. Public Health and Marine Hospital Service, to create a National Legislative Council, and a National Auxiliary Congressional Committee, and make such rules not inconsistent with the constitution and by-laws of this Association as it may deem desirable for their government."

In order to comprehend the meaning of this sentence, answers to the following questions would be indispensable: 1. What kind of State and local societies are to be cooperated with—medical, literary, religious, industrial, or what? 2. What chief officers of the Army and Navy are to be cooperated with? As the President is the commander-in-chief of the Army and Navy, how far down the line of chief officers must the cooperation extend? If cooperation with *medical* officers was meant, it should have been so stated. 3. After the cooperation provided for has been secured, how are a "National Legislative Council" and a "National Auxiliary Congressional Committee" to be created? Inasmuch as a "Legislative Council" must be one that legislates, and a "Congressional Committee" one that originates in Congress, it is feared that any attempt to reason from titles to duties would result in confusion and obscurity. After getting answers to the above questions and pursuing the sentence further, it develops that the original Committee on Medical Legislation, consisting of three, is authorized to make the rules for the government of the bodies created, although each of these might easily consist of forty or more members and might contain high officials from the President of the United States down to an undefined limit. Did an oligarchy ever enjoy more power?

Without stopping to point out other anomalies in this section, attention is called to sub-section 4 of section 11 in the same chapter, which is in these words: "(4) A Committee on Legislation and Political Action, to which shall be referred all matters relating to State and National Legislation, Memorials to Legislatures, to the United States Congress, to the President of the United States, etc. (The members of the National Committee on Medical Legislation shall be members ex-officio of this Committee)." Herein another committee, having precisely the same jurisdiction as that conferred on the "Committee on Medical Legislation," seems to be provided for. True, the members of the latter committee are made ex-officio members of the former one, but if providing for two committees with the same jurisdiction does not create confusion, then what shall it be called?

Leaving other curiosities in this chapter unmentioned and passing over several chapters, the subjects of which belong to the constitution and not to the by-laws, we tarry long enough to call attention to the fact that under the chapter devoted to "Publication" the term "executive committee" occurs five times—important duties being imposed upon said committee—and yet in the chapter devoted especially to "Committees" no committee entitled "executive committee," is provided for. The question very naturally arises as to how the important duties imposed are to be discharged when the committee named to discharge them has no constitutional existence?

Under the head of "Amendments," on the last page of the by-laws, the climax of "curios" is reached in the following provision: "The House of Delegates, at any annual meeting, wherever the same may be held, may instruct the Board of Trustees to make any changes in the articles of incorporation in accordance with the law, which may appear desirable, or which may be made necessary by any change or amendement to the constitution and by-laws of this Association."

It is a question as to whether the logic or the syntax of the above quotation is the more remarkable. How the Board of Trustees of the American Medical Association could be expected to make changes in Articles of Incorporation granted by the sovereign state of Illinois is utterly beyond the comprehension of the writer, indeed, is a colossal absurdity!

This review of the alleged Constitution and By-Laws of the American Medical Association might have been made much more exhaustive, but enough has been said, perhaps, to show that, judged from a literary and logical standpoint, they are far below the plane they should occupy. It is fortunate, therefore, that they are null and void.

The experience acquired during the past five years of effort to improve or perfect organization should be a valuable teacher, and should point with luminous certainty to the road that should be traveled from this time forth.

Turning now to a brief discussion of methods pursued, it is evident that many of the members of the Association have not realized the weighty obligation that rests upon them personally to give the subject of organization earnest thought and close attention until carried to a high degree of perfection and efficiency. Many are deeply absorbed in the scientific work of the Association, forgetful, perhaps, that achievement in this field depends largely upon correctness and perfection of organization. One of the natural and inevitable results of inattention on the part of a large proportion of the members of the Association to the principles and details of organization is that the control of affairs has been largely usurped by an oligarchy. The delegate who has not observed this must be blind indeed! In truth, the delegates themselves are responsible for this condition of things and can promptly cure it by resolving, each for himself, to do his own thinking, and also by refusing to follow except when and where his judgment approves. Leadership is a magnificent and imperial endowment when it comes through a happy combination of wisdom, courage, and unselfishness. Such a leader will attract, and ought to attract, loyal and enthusiastic followers, and with such support may win great victories in behalf of truth and right. If leaders are to be followed, let us see that they are preeminently endowed with qualities that entitle them to lead.

The House of Delegates, and at least one of its standing committees, has on several occasions shown a strong disposition to overstep the line of demarcation that should sharply divide the authority of the national body from that of the State organizations. Allusion is had to a disposition to deal directly with the county societies, instead of with the State organizations. Several notable instances of this kind could be pointed out. A brigadier-general who should communicate officially with the captains of companies in his brigade, instead of with the colonels of the regiments, would soon overthrow all discipline and bring disorder and discord. The same rule should apply to the case under discussion, and unless it is scrupulously adhered to, all harmony of organization will soon be destroyed.

When the fourth edition of the "New Constitution" was submitted for adoption at the Atlantic City meeting of last year, the writer, relying upon justice and right, raised the point of order that it would be illegal and unconstitutional to adopt the document at that meeting, contending that it must lie over to the next annual meeting in order to admit of mature consideration. The point of order was overruled by the president, whereupon the question for adoption was put by a *viva voce* vote and declared adopted, when, according to the real and existing constitution, unanimous consent would have been required for adoption, and according to any of the editions of the alleged "New Constitution," a two-thirds vote would have been required. The procedure, therefore, was simply a mockery.

Nothing was left for the writer to do but to submit a protest. This he did in the following terms, a number of other gentlemen uniting with him:

*To the President and Members of the House of Delegates of the American Medical Association:*

The undersigned, delegates representing, wholly or in part, the affiliating organizations of the following named States, to wit, Alabama, Tennessee, Georgia, North Carolina, South Carolina, Mississippi, and New York, desire to place themselves on record as expressing the unqualified opinion that the recent action taken by this body in adopting a new constitution and by-laws was in open and direct violation of a provision of the existing constitution and by-laws, and therefore is illegal and void. The provision to which reference is made reads as follows: "No amendment or change in the constitution and by-laws shall be acted on until it shall have been presented at a previous annual session."

Upon comparison of the two constitutions in question, we find that the text of the new one differs in many and material points from that of the former one; neither do we find in the minutes of the last annual meeting of the Association, as published in The Journal of the Association, any record of such changes having been submitted to the Association. Further, we find in the official minutes of the last annual meeting of this Association the following resolution: "Resolved, It shall be a standing rule of the Association that no amendment or change in the constitution or by-laws shall be acted on unless it shall have been presented at a previous annual session."

Believing for the reasons given that the action complained of was precipitate and unconstitutional, therefore unwise, we beg that this protest against said action shall be spread upon the minutes of this meeting, and published along with the other proceedings.

All of which is respectfully submitted.

Signed: W. H. Sanders, L. C. Morris, W. H. Robertson, Delegates from Alabama; Duncan Eve, J. T. Herron, Delegates from Tennessee; J. B. Morgan, Floyd W. McRae, Delegates from Georgia; J. W. Grosvenor, Delegate from New York; J. Howell Way, Albert Anderson, Delegates from North Carolina; W. H. Harrison, Delegate from Mississippi; E. L. Patterson, Delegate from South Carolina.

When the above protest was submitted, motion was made to lay it on the table, which motion was promptly adopted.

The right of protest is one universally conceded to members of deliberative and legislative bodies, and perhaps no other instance than the above is on record in which this right was either questioned or denied. Indeed, so precious and valuable is the right of protest esteemed that it is often embodied in the constitutions of States. Under the circumstances related, was not the action of the House of Delegates the rankest despotism? An organized body of American citizens denying to a number of its members the inherent and inalienable right of a freeman—the right of protest! Such tyranny and under such circumstances is almost beyond belief!

A few words, personal to the writer, and this discussion and review will be finished.

The position of a fault-finder is generally an unenviable one, but sometimes convictions are so profound that no alternative is left but to assail, be the consequences what they may. So is it in this instance.

When the first edition of the "New Constitution" appeared in print the defects of principle and detail stood out with glaring and disappointing prominence to the writer. Throughout this discussion he has relied largely upon notes and comments made upon the "New Constitution and By-Laws" in 1902.

Wishing to promote, and not to hurt, organization, he sought to find private avenues through which he might reach the "powers that be," and point out to them wherein in his opinion the organic law might be improved. Failing utterly in this effort, he waited for some opportunity to arise of which he might avail himself to carry out his purpose. None came until the fourth edition of the "New Constitution" was submitted to the Association at the Atlantic City meeting of last year. This document, after having been submitted by the "Committee on Constitution," was referred to a larger committee, and an invitation was extended to any members of the Association who might desire to be heard to appear before the Committee. The writer availed himself of this invitation and was accorded a hearing by the Committee. He proceeded to point out what appeared to him some of the obvious defects in the Constitution and By-Laws, whereupon, he was ruled out of order and the hearing terminated. Before leaving the room, however, he was informed that he would have the privilege of looking up the Chairman of the Committee at his hotel the next morning and stating to him individually any views he might wish to submit in regard to the Constitution and By-Laws. It is needless to say that this gracious privilege was not utilized!

The Committee reported the next day favorably on the new draft of a Constitution, whereupon, as has been explained, the writer raised the point of order that the House of Delegates could not violate an existing constitution in order to adopt a new one. His point of order was overruled, and the fourth edition of the "New Constitution" was rushed through in open and direct violation of both the old and real constitution, and what was believed to be, at that time, the existing constitution.

The writer yields to no one in his desire to see the American Medical Association grow great and prosperous, but he is at the same time profoundly convinced that this cannot occur in any other way than by formulating and adopting a constitution based upon philosophical principles and logically put together from foundation to dome.

For a quarter of a century he has been closely identified with a State organization whose constitution is thirty-two years old, the principles and details of which were conceived and embalmed by the genius and fertility of Jerome Cochran, the profoundest thinker and philosopher on the subject of medical organization that this, or any other, country has ever produced. With such a teacher and such an experience, it is not strange that his ideals should be high and that his ambition for the American Medical Association to occupy the lofty plane to which it is entitled should be genuine and pure.

The scientific workers in the Association have been for many years, and are still, doing magnificent work; it only remains for the legislative and executive departments to do correspondingly well. That this can be done does not admit of the shadow of a doubt.

W. H. Sanders, M.D.

## PNEUMONIA SIMULATING APPENDICITIS.

To the Editor of the Medical Record.

Sir:—Some years ago I was called by Dr. Judson C. Smith to see a young woman who had developed symptoms of a violent infection, during the preceding twenty-four hours. There was a marked temperature elevation, rapid pulse, and constant complaint of acute pain in the right iliac region. There was rigidity of the abdomnal muscles, but not in sufficient degree to prevent palpation of the viscera, and the appendix was found in the pelvis, adherent to the right oviduct. There was no chest symptoms. The case seemed to be one of appendicitis, although the appendix was not markedly tender on pressure. This is sometimes a feature of cases of appendicitis in which rapidly occurring gangrene has destroyed the nerves of the appendix. On operation I found a normal appendix adherent to an oviduct which had been the seat of some prior infection. The peritoneum was normal in appearance, and evidently not involved in an acute inflammatory process. On the following day the patient developed a typical right lobar pneumonia, and cultures of pneumococci were obtained. She made a good recovery from the pneumonia, and the operation wound healed by primary union. A week later I was called by Dr. C. S. Elebash in a precisely similar case, but finding the appendix normal on palpation, we discussed the idea of the case being one of pneumonia, and waited. On the following day acute lobar pneumonia was fully in evidence.

Recently I was again deceived, in spite of being on guard against mistake and being familiar with the literature bearing upon the subject. I was called late at night by Dr. J. Seymour Emans to see a boy five years of age, who had bene under observation for four days with symptoms of a violent infection, the character of which could not be made out. A friend of the family had been called in for what seemed to be emergency symptoms that evening, as Dr. Emans happened to be out of reach. The diagnosis of perforative appendicitis, with peritonitis was at once made, and the opinion given to the effect that operation must be done instantly. Dr. Emans coming in later, called me up by telephone, stating that he had not felt that the case was one of appendicitis, but that the case was becoming a very serious one. He had made exclusion of pneumonia and of the acute exanthemata as well as possible. There had been nausea and vomiting, the boy complained much of pain in the right iliac region, the abdominal muscles were so rigid that palpation of the viscera could not be made; the temperature was 100° F. and the pulse 130. the symptoms indicated a grave condition, and while I did not make a diagnosis of appendicitis, my diagnosis was of some acute abdominal infection sufficient to call for an operation, with the possibility of finding appendicitis. Dr. T. G. Bennett was summoned, and I opened the abdomen through a small incision. The peritoneum was not the seat of inflammation at any point, and the appendix was normal. Closure of the abdomen was at once made, without disturbing any of the viscera further than was necessary in feeling for exudate. On the following day a right lobar pneumonia showed itself. Dr. J. E. Winters, who saw the case in consultation, said that he had very recently seen a similar case in which the symptoms of pneumonia had not been in sufficient evidence to admit of classification for several days. A number of cases of pneumonia simulating appendicitis have been reported. Usually the high temperature and absence of marked tenderness of the appendix on pressure would be sufficient to put one on guard, in advance of the appearance of symptoms of cough, pain in the chest, exudate, and other evidences of pneumonia; but in this boy's case abdominal rigidity prevented any special examination of the appendix, and the low temperature and rapid pulse rate were strongly indicative of an abdominal infection of some sort. The chest had been examined with particular care.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

AERIAL CONVECTION OF SMALLPOX—ADRENAL CARCINOMA OF THE LIVER—ADENOIDS.

London, June 9, 1905.

The question of aerial convection as a cause of the spread of disease has lately come up again and has been discussed relative to both sanitary measures and medical theories. The public has long been satisfied that in regard to the spread of smallpox the influence of hospitals is great, and in consequence sanitary authorities have found difficulties in obtaining sites for such buildings. On the other hand, many sanitarians seem still unconvinced that the danger alleged is serious. The Epidemiological Society has devoted two meetings to the discussion of the subject, at the conclusion of which the president, Dr. B. A. Whitelegge, C.B., expressed the conclusion that it was reasonable and safe to admit, and therefore to provide against, all forms of communication of diseases; of these it must be acknowledged that aerial convection was one in many, if not all, diseases, and perhaps it played a more important part in smallpox than in any.

The discussion began with an elaborate paper by Dr. G. S. Buchanan, who said the prevalence of smallpox during the last four years had necessitated the establishment of more isolation hospitals and revived interest in the subject of their influence. He stated the various cases in which a regular graduation of the incidence of smallpox around hospitals had been observed from the time of Mr. Powers' report (1886). He concluded that the observed facts as to diffusion of dust in various circumstances showed the reasonableness of the hypothesis that aerial convection is the cause of the spread of smallpox around isolation hospitals.

Dr. C. B. Kerr said the paper was the best defence he had heard of the aerial hypothesis, but there were facts on the other side. The only isolation hospital in Edinburgh was badly placed—only 72 yards from the fever block, with 400 patients, and 335 yards from the poor-house, with 1,000 inmates, while paupers were at work all day close to its boundaries. The average number of patients in this isolation hospital had been 55 for two months and 47 for three months. Within the one-quarter mile circle was an asylum with 400 patients and a general population of 2,000. Yet within a mile of the hospital there were only two cases of imported smallpox and two secondary in the poor-house. Curiously, there were also two in another poor-house far away. A number of pateints in the fever hospital in the ward nearest the smallpox block were unvaccinated, but none of them took the disease. The nurses for the smallpox wards were volunteers from the fever hospital, and, once in, were not allowed to leave the building. He thought the association of smallpox and fever hospitals advantageous. Old nurses were more to be trusted than new recruits. Just outside the mile limit several houses were invaded, but in three of the first four exposure to infection was proved. The actual epidemic was concentrated round the site of the old hospital, which was blamed for former outbreaks as a center of infection.

Dr. Newsholme criticised Dr. Buchanan's conclusions as to several outbreaks and his method of calculating incidence by the percentage of houses invaded. He pointed out, too, that the wind carrying the infection from one hospital must have already been in the East, and from the other in the West. He would not deny the possibility of aerial distribution of smallpox any more than of scarlet fever or other infectious diseases, but in smallpox it was claimed to be the dominant factor. Personal infection, direct or indirect, should be absolutely excluded before admitting aerial convection.

Dr. Thresh admitted surreptitious communication may have occurred at Purfleet. The first cases appeared before the hospital was opened and subsequent ones around the original focus just as in St. Pancras, where there was no hospital.

Dr. Niven agreed with Dr. Buchanan's paper, and further held that hospitals were more dangerous when occupied by acute cases.

Dr. E. W. Hope said all cases were acute at first and the unvaccinated were most infectious during scabbing and convalescence. But the mildest cases contributed to the spread. Round the Park Hill Hospital at Liverpool, twelve distinct outbreaks occurred before the opening and nine afterwards, and of four of these nine were traced to infection elsewhere. The maximum incidence was shown by the map to be when the hospital was empty.

Dr. McVail, referring to Dr. Kerr's Edinburgh experience, remarked that inmates of schools and asylums should not be compared with the general population, as they were mostly recently vaccinated.

A paper by Drs. S. Phillips and B. Spilsbury was read at the Clinical Society on a case of primary adrenal carcinoma of the liver, in a woman of 40, who died after a fortnight in hospital. On admission there was enormous ascites, wasting, and debility. Paracentesis gave 386 ounces of clear yellow fluid, after which the liver could be felt greatly enlarged with nodules all over it of various sizes. Other nodules in peritoneum and omentum. It was found at autopsy that the left lobe of the liver was almost replaced by firm, white nodules of all sizes. Right lobe similar but less extensive growth. Others attached to peritoneum. The adrenals were normal. Microscopic specimens exhibited at the meeting showed the growths had the characteristics of carcinoma originating in adrenal cortex. Aberrant "rests" of suprarenal tissue have been described by several observers since Schmorl described such in 1891. They may consist of cortical or medullary substance and may give rise to neoplasms of epithelial

type, reproducing the structure of adrenal tissue. Pepere first recorded malignant disease of the liver thus arising, and the present case exactly resembled his, both clinically and pathologically.

At the Clinical Society, Drs. F. Taylor and J. Fawcett related a case of milky ascites in which the opalescence was not due to fat. Paracentesis was performed nine times and the fluid was always milky. At first this was put down to fat, but under the microscope no globules were seen. The fluid was found post mortem in both pleuræ as well as in the peritoneal cavity—analysis showed fat only .045 p. c. Some proteid was considered the cause of opalescence which had been ascribed by others to (1) lecithin, (2) mucoid substances, (3) a proteid like casein, (4) a combination of lecithin and a proteid.

Mr. Jas. Berry read an account of a case of syphilitic destruction of the left ala of the nose. The ulceration had healed under iodide and an artificial ala fitted and worn for three months, but as the patient wished to go abroad and have something else done a plastic operation was performed which was successful and left only a linear scar in the furrow between the nose and cheek, and was not very noticeable. It was remarked by members that plastic operations in syphilitic cases gave only poor results, and the longer the interval after inoculation the less satisfactory. One member advised a three years' course of mercury in this case.

Throat specialists do not take a narrow view of their branch—they are rather driven towards expansion with the persistence of territorial empires. Thus laryngology has absorbed rhinology and threatens to appropriate otology. In the course of its progress adenoids naturally fell to its share, and the energy with which these growths have been traced is characteristic. The specialty has not only impressed other branches of the profession, but excited the attention of the public until it is no uncommon event for parents to take their children to a throat hospital to "have their adenoids removed," though the parental diagnosis is not always correct, being founded on snoring, mouth-breathing, deafness, or some equally uncertain symptom. In London, therefore, there is not much danger of adenoids being overlooked, and one might have supposed that the same might be said of the country, for provincial practitioners are quite awake on the subject. However, a discussion on this point has been raised at one of the laryngological societies, and a resolution proposed and seconded to appoint a committee to investigate the prevalence of adenoids in the child life of the country and its effect on national stamina. We have heard enough lately of our national decadence, but one hardly suspected adenoids to be an important factor in this improved deterioration. Some enthusiasts seemed to think national authorities might take up the matter, but others thought it would be no use to expect any help from rate-payers who are already so heavily burdened, or even from officers of health who are handicapped with other work. Some who did not support the resolution offered a mild sympathy with any proposal to collect accurate statistics, and others testified that there was no lack of information on the disease among country practitioners and no inability to deal with it. It was pointed out that in rural districts where the children led a more outdoor life and in purer air we might expect that adenoids would be less common, if anything, than in towns, and some impressions in this sense were stated. The resolution, when put to the meeting, was lost, so the injury is left to individuals interested enough to collect statistics for themselves.

## OUR PARIS LETTER.

**(From Our Special Correspondent.)**

RECEPTION OF ENGLISH PHYSICIANS AT PARIS—CONGRESS OF THE FRENCH SOCIETY OF OPHTHALMOLOGY—CONGRESS OF THE FRENCH SOCIETY OF RHINOLOGY, OF OTOLOGY, ETC.—ADENOPATHIES—THE MICROORGANISM OF SYPHILIS—ILLEGAL PRACTICE OF RADIOTHERAPY—TRAUMATIC DELIRIUM—OBITUARIES.

PARIS, June 10, 1905.

THE reception for the English physicians has been most successful, two hundred attending. The visitors were delighted with the cordial welcome which everywhere awaited them. The program of entertainment which was given in our last letter was carried out in every detail. Opportunity was given to the English physicians to come in touch with every part of the French medical world. The reception at the Sorbonne was most brilliant. Liard and Bouchard welcomed the visitors with great cordiality, Sir William Broadbent, Professor Clifford Allbutt, and Mr. Olgivie replying for the guests. Not less successful was the reception at the Faculté. With great eloquence the Dean Debove welcomed the guests, reminding them that in the medical world both English and French met upon common ground, the very walls of the Faculté saluting them. Next they were received in the magnificent salons of the Hôtel de Ville by the President of the Municipal Council, assisted by the Prefect of the Seine and the Prefect of Police. In the free intervals which were left them the guests visited the various hospitals and clinics. Every evening they were invited to dine by members of the French committee and by personal friends. The excursions to Chantilly, Vichy-Evian, Biarritz, Pau, Cauterets, Salies, etc., were of the greatest interest to those who participated in them.

The soirée at the Automobile Club, and the banquet at the Grand Hotel, in which five hundred participated, were very happy events. The orators of the evening rivaled each other in giving toasts, and the enthusiasm of all present was at its height when Bouchard announced that Sir William Broadbent, President of the English Committee and Physician to the King of England, had just been nominated Commander of the Legion of Honor.

At the same time with the reception to the English Physicians, two congresses met at Paris—that of the French Society of Ophthalmology, and that of the French Society of Rhinology, Otology, and Laryngology. One of the most interesting questions discussed by the French Society of Ophthalmology was without doubt that of the complete correction of myopia, in which Bourgeois of Reims laid down the rules for such correction.

At the French Society of Rhinology, Otology and Laryngology, Gellé read a paper on "Adenopathies in the Affections of the Nasal Fossæ and of the Nasopharynx." This work comprised two parts; the first was devoted to the study of the anatomy of the lymphatic net-work, the afferent trunks, and the neighboring glands, according to the most recent researches; the second, which was the clinical section, showed when and how in the presence of acute or chronic infections of the nasal fossæ the glands react. At the same meeting Lombard gave his report on "The Operative Indications in Certain Clinical and Anatomical Farms of Frontal Sinusitis."

The Academy of Medicine at its meeting on May 16, listened to a communication concerning the microbe of syphilis. Schaudinn and Hoffmann, in a recent number of the *Deutsche medizinische Wochenschrift*, published a paper dealing with the bacteriology of syphilis. They sent their preparations to Metchnikoff and the fame of this work was spread abroad, arousing public curiosity. Metchnikoff and Roux declared to the Academy that the researches of Schaudinn have resulted in the discovery of a spirochæta which ought to be considered as the true pathogenic agent of syphilis. These researches have had as a point of departure the work which was undertaken to verify the existence of a minute protozoon described by Segel at the beginnig of 1905. Schaudinn was not able to find the protozoon in question, but his attention was attracted by spirilla of two varieties: *Spirochæta refringens* and *S. pallida*. In twenty-six cases studied by Schaudinn and Hoffmann, the *S. pallida* was always found. In eight examinations of fluid extracted by glandular puncture the result was always positive. Metchnikoff and Roux have made control experiments on the monkey. In six of their animals they four times found the *S. pallida*. One of the negative cases was explained by the fact that the monkey was on the road to recovery. In the other case the observations are not yet concluded. In the comparison of the preparations the absolute identity of the spirochæta found in man and that found in the monkey has been confirmed. On examining the fluid obtained by scraping the papules of secondary syphilis in man the parasite was found in evidence four times out of six. The examination of the scrapings from acne, from the itch eruption, and from psoriasis did not determine the presence of an analogous parasite. Summing up their results, Metchnikoff and Roux believe that one can count on finding in those researches an element of diagnosis in syphilis, especially by the employment of the method of Marino which stains the organism in a quarter of an hour. As to the cultures, it is entirely too soon to speak of those, but the mass of the actual data argues in favor of the fact that syphilis is a chronic disease due to the presence of *Spirochæta pallida* (Schaudinn.)

Professor Debove has drawn the attention of the Academy to the free practice of radiography by men who have not the least notion of this science. The Röntgen rays have given undeniable therapeutic results, but they can also cause various accidents; serious radiodermatitis, scars, and in women, atrophy of the ovaries and consequent sterility. It may be that this last effect will soon constitute a true social peril. Debove, reminding the Academy that the Röntgen Congress held at Berlin had just unanimously voted that the employment of Röntgen rays in man belonged only in the province of physicians, proposed to nominate a committee, the members of which should study this question and should see if it is not legitimate to ask the authorities to prosecute such persons who, while not possessing the diploma of a doctor of medicine, are making use of the Röntgen rays in the treatment and the diagnosis

of disease. The Academy unanimously approved of the proposition and nominated a committee.

At the same meeting the Academy took up the election of two foreign associate members. They elected Ehrlich of Frankfort, and Ramon y Cajal of Madrid, whose investigations in neurology are known to the entire world.

The Surgical Society devoted parts of two meetings to an interesting communication on post-traumatic delirium. Picqué attempted to demonstrate that delirium tremens as observed in certain subjects as a consequence of traumatism was not always an alcoholic delirium, but generally a delirium of infectious origin. The conclusion reached from his study of this subject was that the delirium appeared generally only when the infection was apparent and disappeared at the same time with the infection. Only the absence of all infection can authorize one to make the diagnosis of pure alcoholic delirium tremens. Inasmuch as most of the cases are of infectious origin and as such are relieved by surgical methods, care should be taken to place these patients under the care of a surgeon and not send them to asylums for the insane.

Professor Berger presented two reports on interscapulothoracic amputation for malignant tumors of the scapula and upper extremities of the humerus. He declared it to be an excellent operation, easy and certain of execution, exposing the patient to only slight risks of death, and yielding a large number of permanent good results, and even some definite cures. He said that in a majority of these cases immediate relief was experienced and life was sufficiently prolonged to make the operation worth while.

At the Hospitals Medical Society, Jacquet and Sevin, of Leipzig, presented a communication at the meeting on May 19, in which they declared that their search for the spirillum of Schaudinn in a large number of cases of tertiary syphilis had been without success. On the other hand, in the case of secondary lesions they habitually found it. At a previous meeting Jacquet reported an interesting observation on the cutaneous syndrome of gastrointestinal origin, cured by alimentary hygiene.

The Hospitals Medical Society at its last meeting held a memorial service for one of its distinguished members, Maurice Soupault, a physician of the Paris hospitals, who died just as he was going to publish an important work on the diseases of the stomach, a line of investigation to which he had given special attention. We have also to note, with equal regret, the death of another learned man, little known to this generation, but whose fame should be universal, namely, Paquelin, the inventor of the thermocautery.

## Progress of Medical Science.

*Boston Medical and Surgical Journal, June 22, 1905.*

**The Preservation of the Urine.**—From an elaborate series of experiments with various substances employed to keep urine from spoiling, J. B. Ogden arrives at the following conclusions: (1) Boracic acid is the most practical urinary preservative that we possess when used in the proportion of 5 gr. to 4 oz. (or 2½ gr. to 2 oz.) of urine. (2) Formaldehyde solution should be used only by the physician or a responsible person. It should be remembered that one drop of the solution will preserve a pint of urine for about a week, and that one drop can be used in 4 oz. of urine without harm. (3) Other substances than boracic acid and formaldehyde should not be used. (4) The name of the preservative and the quantity that has been used should always accompany the specimen to be examined.

**Impetigo Contagiosa.**—J. T. Bowen refers to this disease as a collection of "cutaneous abscesses caused by pyogenic microorganisms." He describes the evolution of the lesion which is found between the lower horny layers and the rete. So far as concerns its relation to eczema, we know that the latter may have been produced by a long continued impetigo, or an eczema may become infected with the pus cocci. Staphylococci generally predominate. Energetic treatment may be resorted to, as only the superficial layers of the skin are involved. Soap and water, so highly injurious to the sensitive, inflammatory eczema of child or adult, should be freely used. Removal of the crusts by this means twice a day, followed by the application simply of a 10 per cent. ointment of boric acid in lanoline or lard is, in a large majority of cases, sufficient for a cure. Much stress is laid upon the thorough removal of the crusts with soap and water. Certain cases, especially those of the adult type, will require a more energetic treatment, and an ointment of sulphur, or, where the affection is not extensive, the ammoniated chloride of mercury may be used with effect. Very strong parasiticides should be avoided, as a rule, as unnecessary, and as tending to produce a dermatitis. Complication with eczema calls for great caution lest too vigorous treatment be instituted.

**Scabies.**—J. S. Howe declares that the average general practitioner often fails to make a correct diagnosis of this condition. He describes the parasite causing it, and says that atypical forms of the affection often occur in the cleanly and well-to-do, and that under these circumstances the diagnosis is not always easy. The lesions are scanty, and are nearly always discrete papules or vesicles, or both combined, and of pinhead size. Burrows in the skin are rarely found. An urticaria often accompanies the scabies, and a diagnosis is made of the former malady. The author prefers the following plan of treatment. The patient should, on retiring, take a hot bath, and scrub himself thoroughly with soap and water. After the body is dried, on ointment, consisting of napthol, B 3i; sulph. flour, 3ii; balsam Peru; vaseline, aa 3i should be rubbed thoroughly into all the affected parts. This process, omitting the bath, is to be followed on the two succeeding nights. If this is thoroughly done, the patient should be cured. In infants and persons with delicate skins, prone to dermatitis and eczema, balsam of Peru is very effective and less irritating than the ointment before recommended.

*New York Medical Journal, June 24, 1905.*

**The Demonstration of the Flagella of Motile Bacteria and a Simple Method of Making Microphotographs.**—E. W. Duckwall mentions the following requisites for the proper demonstration of flagella: Culture to be made on 2 per cent. agar from young growth in bouillon. Suspensions in water to be made according to nature of organism. Coverglasses to be absolutely clean. Mordant to be used only when fresh. Dye to be made fresh, and used while warm. Spread on coverglass not to be confluent. Fixing to be done without injury to flagella. Staining to be done without overheating. Washing with alcohol and water without breaking the film. Clearing with xylol after thorough drying. Mounting in xylol balsam without previous examination. His paper is an elaboration of these rules, and is illustrated by several excellent pictures, which attest to the value of his methods. As to making microphotographs, he finds a camera about twice as long as the ordinary four by five inch camera, used in a horizontal position, to fulfill every need. The best plates are the isochromatic or orthochromatic swift plates, which are corrected for colors. He has found the acetylene radiant preferable to gas, oil, or electric light. It is slower than electric light, but brings out all details with wonderful nicety. The only screens he uses is green glass. Printing from the negatives on glossy velox brings out the best detail. The glossy velox is then ferroplated, which makes a beautiful photograph.

**Anesthesia in Throat Surgery.**—H. Wallace discusses the relative advantages and dangers of chloroform, ether, and gas, under the conditions named. His belief is that for the operator, the gas-ether sequence with narcosis pushed well to palatal relaxation, the patient being in the dorsal position with moderately lowered head, secures the best results as regards least danger to the patient and the greatest facility of operative technique.

*American Medicine, June 24, 1905.*

**Bromides in Epilepsy.**—Frederick Peterson states his object in bringing this subject before the profession is to excite a general antipathy to the indiscriminate use of this drug in epilepsy. He believes that as a rule this drug is worse than the disease. The sum total of comfort, happiness, and well-being of the epileptic would have been greater if the bromides had never been discovered. When the drug is to be employed, it should be used in small doses, combined with some of the harmless remedial agents, or instead of the bromine salts, some preparation of brominized oil, which is less powerful and less noxious, should be given.

**Treatment of Incontinence of Urine in Children.**—Noble P. Barnes explains the physiology of evacuation of the bladder in early infancy. Delay in controlling the urinary function beyond the period of dentition becomes an abnormal condition termed enuresis. He divides the causes into organic (including anomalies, injuries, and diseases) under four headings; and functional, under seven headings. Successful treatment is determined by etiologic factors. Close attention must be given to diet, hygiene, habit, and training. Medical, mechanical, and mental treatment are discussed.

**Treatment of Appendicitis in the Precarious Stage.**—J. G. Sheldon believes that operation, not through an anterior incision, but through Petit's triangle, should be the method of choice in treating appendicitis in which the inflammatory process has invaded structures beyond the appendix, and is not localized. This operation offers little risk of contaminating the small intestines; it provides efficient drainage, and is not liable to be followed by hernia. It is

believed to be more efficient in treating precarious cases of appendicitis than the expectant plan of treatment, or operation through an anterior incision.

**The Therapeutic Value of Ergot in Labor.**—J. C. Applegate does not regard ergot as an appropriate or safe remedy at any period during labor, until the presentation or expulsion of the placenta, notwithstanding the statement in many textbooks that it is valuable for uterine inertia. Its physiological effects on the uterus are unlike the rhythmical labor contractions in that they are less intermitting, more continuous, and predispose to constriction, particularly of the lower segment. Paralysis of the fetal heart from compression, retention of the placenta and membranes, and rupture of the uterus are the attending dangers. Complications of the third stage of labor or post-partum hemorrhage rarely follow the expression of the placenta after the Credé method. He regards ergot as valuable at the end of the third stage of delayed labor or when uterine inertia has been a factor, also after placenta prævia and reposition of an inverted uterus. With a uterus normally contracted, the author considers it valueless and rather detrimental when used for the prevention of septic infection, since its tendency is to disturb the venous thrombi and lock too completely within the uterus excreta that would otherwise be liberated. Ergot may be administered by the mouth as a safeguard, but for the control of hemorrhage better results are obtained by hypodermic administration.

**Gunshot Wounds of the Stomach.**—W. M. Jordan advocates immediate operation in cases of suspected wound of the stomach. If the stomach is full at the time of operation, he advises syphoning its contents by means of a tube passed through the bullet wound. For closing the perforations, a purse-string suture of silk is recommended, which is reinforced by a second one in order to add strength as well as to increase the approximated area. Nothing whatever should be given by the mouth during the first week, the patient being sustained by nutrient enemas, and water being given by subcutaneous and rectal injections of normal salt solution. Morphine is given for a few days to limit peristalsis and check gastric secretion. A wound of the posterior surface of the stomach constitutes a positive indication for drainage of the lesser cavity of the peritoneum, the presence of such a wound being taken as presumptive evidence of injury to the underlying pancreas or left kidney. Two cases are reported, the first having a single perforation on the anterior surface, with subsequent recovery, and the second presenting two perforations on the anterior surface; death from shock occurred four hours after operation.

*Journal of the American Medical Association, June 24, 1905.*

**When Not to Operate for Appendicitis.**—J. E. Moore combats the dictum that all cases of appendicitis are operative cases, and holds that while certain classes of cases, such as chronic appendicitis without acute attacks, those with localized abscess and acute cases seen in the beginning of the attack, call for operation provided hospital facilities and a good surgeon are available, there are some other cases in which surgical interference is not advisable. The conditions in which the radical operation is not the best treatment are summarized by him as follows: "First, when the patient is evidently moribund; second, when the patient is evidently convalescing; third, when certain grave complications are present; fourth, in the midway cases beginning with the third day when the physician and surgeon are in doubt; fifth, in the extreme cases of suppurating peritonitis." Even in serious complications, or when general anesthesia is contraindicated by the condition of the patient, if localized abscess exists, he states that it should be evacuated under local anesthesia. Ochsner's starvation treatment, Moore says, has been badly misunderstood. Ochsner did not recommend starvation and lavage for appendicitis, but for spreading peritonitis due to neglected appendicitis. In such cases Moore, by opening abscesses locally, and by using to a greater or less extent Ochsner's method, has been able to tide them over to a successful interval operation.

**Bright's Disease.**—Bright's disease, according to A. C. Croftan, is a toxemia presumably of intestinal, and, by implication, of hepatic origin, involving, primarily, the cardiovascular apparatus, and secondarily, many organs of the body, including the kidneys. Casual treatment, therefore, in his opinion, must be directed toward the digestive disorders that underlie most causes of the disease. Symptomatic treatment is not the conventional treatment of the kidneys, but the treatment of the heart and arteries. When nephritis is established, it, of course, calls for treatment, but nephritis may not occur till late in the disease. The general measures of maintenance of the nutrition by regulated diet and the avoidance of nervousness, care, worry, and fear, are naturally of paramount importance. Croftan advises the use of intestinal antiseptics, sulphocarbolate of zinc, sodium glycocholate, and organic peroxides, together with bismuth as a test for the presence of sulphur compounds in the feces. When the stools are not colored black by bismuth sulphide it is an indication that the intestinal antiseptic is given in sufficient amount to check the putrefaction of albumin, and in most cases the indican and other aromatic urinary ingredients also will have disappeared. Small doses of digitalis, one drop of the tincture, t.i.d., are useful in rendering the heart less susceptible to the disturbing stimulation of circulating toxins, and may be given without danger of impairing the power of the heart to respond to larger doses in emergency. Continuous vasodilatation, lowering blood pressure in the kidneys, reduces the albuminuria and enables the renal epithelium to regain its tone and to resume its functions. Other measure that aid are hot baths, rest in a warm bed, and judicious life in a warm, dry climate, all favoring relief of arterial tension and rest to the heart. Croftan condemns kidney decapsulation as irrational in Bright's disease. In acute nephritis underfeeding is advisable, but in chronic cases the daily amount of feeding, expressed in calorie values, should be inversely proportionate to the presumed duration of the nephritis. There is no reason why a mixed diet may not be allowed in these cases, excluding only such foods as produce substances difficult of elimination by or irritating to the kidneys. A milk diet is good in the acute disease, but injurious in chronic cases, and the excessive water drinking, so often advised, is irritating to the kidneys and injurious to the overtaxed cardiovascular apparatus. Sweating a nephritic patient may be of some value in relieving the patient of excess of water which the kidneys cannot dispose of, but giving much water at the same time is irrational. The restriction or withdrawal of chlorides is useful.

**Circumcision.**—G. T. Vaughan attaches three hemostats to the preputial margin, one at the frenum and the others at the sides, in such a way that when traction is made the inner skin of the prepuce is tightly stretched and the outer skin is lax or nearly so. While an assistant keeps the parts on the stretch, he cuts off squarely the portion beyond the glans, slits up and trims the remaining hood of inner skin covering the glans and unites it to the outer skin by a continuous suture of fine catgut, securing with the suture any bleeding vessels. The blood is then wiped off and the foreskin pulled forward to cover two-thirds of the glans, and the patient put to bed. No dressing is required. The advantages he claims for this method, are: the line of union is covered and protected from infection; no dressing is needed; little or no danger of adhesion of the prepuce to the glans, or of contraction of the preputial orifice. The glans is left partially covered as it should be, and plenty of skin left to meet the varying conditions of the organ.

*The Lancet, June 17, 1905.*

**The Advantages of a Purin-free Diet.**—W. A. Potts says there are few types of chronic disease that are not benefited by a diet from which such substances as meat, fish, tea, coffee, mushrooms, asparagus, and the pulses are excluded, these being the ones which contain purin bodies in appreciable amount. In some instances no other treatment is so efficacious and there are now on record numerous cases in which no improvement took place during years of treatment on conventional lines, while the adoption of the diet under consideration has in a period varying from six months to two years, effected a permanent cure. The purin-free diet is also, he says, a useful adjuvant in the treatment of disorders of a less chronic nature, and especially of those that are generally designated as gouty, rheumatic, or neurotic. In advising such a regimen, it must be remembered that though a vegetarian diet may be made purin-free it is not the most desirable, nutrition and vigor being maintained with difficulty. Meat should be replaced by something of greater calorie value, such as cheese; while if purin-containing substances are excluded, there is no necessity for vegetables. The staple food should be selected from milk, cheese, nuts, and cereals, with fruit as a sauce. Great variety is possible. The author reports several cases in which more or less benefit followed after the institution of a purin-free diet, and concludes that, although this method of treatment is simple in the extreme, yet it requires care and discrimination in its application, and at first, at any rate, the patient must be kept under constant observation. However careful the explanation, there is often some misunderstanding; and minor troubles, such as constipation and difficulty of digesting certain foods, frequently develop in the early days of treatment. To insure success thorough mastication must be insisted on. The change of food must be made gradually, not more than one meal being altered at a time, in the manner suggested by Haig. At the same time careful records should be kept of the weight and other clinical tests instituted, so as to measure the progress. If care is taken in such matters this method of treatment will be found of real value and deserving more general application than it has yet received.

**Some Surgical Notes on Tuberculosis of the Kidney.**—Howard A. Kelly names three avenues of access to the kidney by which tuberculosis may reach it. By the blood; by

ascending the ureter; by direct extension from some contiguous organ. Without any doubt, the writer adds, the infection of the kidney is almost always hematogenous. The focus of the disease is often found in the thorax. The condition of the lungs should always receive the most careful attention. The diagnostician has to consider if the patient has a tuberculosis of the urinary tract; if the disease is still localized; and, if the diseased kidney is removed, whether the remaining kidney is able to do the work. The most difficult cases to diagnose are the early ones, in which the bacilli are often sparse or appear in the urine only at considerable intervals. In obscure cases the urinary sediment should be injected into two guinea pigs. The injection in one should be made into the peritoneal cavities, and in the other under the skin of the groin or axilla. The writer prefers to all other methods the direct aëroscopic examination of the bladder. By catheterization, the appearance of the ureteral orifice and the thickened ureter should be determined. It should be remembered that a simple pyelitis is not infrequently present in the opposite kidney. The opposite ureter may be markedly thickened and still the kidney be free from tuberculosis. The condition of the bladder should be noted as having an important bearing upon the operation and the subsequent treatment. The urea coefficient of the opposite kidney should be determined. The enlarged kidney found in the loin may be the one functionally enlarged and, therefore, the only sound organ. Radical treatment in every case that will permit it, is indicated.

*British Medical Journal, June 17, 1905.*

**Acute Abdominal Symptoms.**—W. Watson Cheyne emphasizes the responsibility of the physician in the treatment of an "acute adbominal illness." First, the diagnosis must be made as quickly as possible, and next the advisability of immediate operative interference must be decided upon. The most prominent symptoms of such an illness are severe abdominal pain, vomiting, and more or less collapse. In many cases, in which surgical treatment is necessary, and is too long delayed, the danger of the patient is greatly increased. It must also be remembered that unnecessary surgical intervention may have disastrous results. The writer briefly reviews the most prominent symptoms. The character and situation of the pain will often give most valuable indications. The chief points to be noted in regard to this symptom are its severity and position, whether it is constant or spasmodic or both, whether it is localized or diffuse, and whether the spasmodic pain is intestinal or not. In perforations of the stomach, intestines, and so on, the pain is usually severe, constant, and of a burning character. In rupture of cysts, the pain from the first is more diffuse and not so severe. Renal or ureteral pain shoots down to the scrotum and thigh. Tenderness may vary according to pressure or percussion. In cases of inflammation and rupture it is marked from the first, and is generally greater on percussion than on pressure. The reverse is true in the case of strangulation. Although the seat of the disease is generally indicated by an area of marked tenderness, this is not always so. Note should be made as to whether it is limited or not, and as to its tendency to spread or remain localized. Rigidity of the abdomen is marked in peritonism. Vomiting is not of any great diagnostic value as a symptom when the patient is first seen. Its persistence is of great importance. This indicates some mechanical obstruction. Collapse is very indicative of a rupture or of an internal strangulation or hemorrhage, and may be marked. As a rule, the occurrence of a rigor or chilliness at the commencement indicates some inflammatory condition, and not infrequently ushers in an attack of appendicitis. A common symptom in all of these conditions is increase in the pulse rate. A rate of 120 or over indicates a serious state of affairs and is in favor of surgical intervention. As a rule, too, a small, running, and irregular pulse is a very bad sign. Elevation of the temperature in the early stage separates inflammations from strangulations, hernias, twists, and so on. The presence of free gas in the abdomen is always a sign of rupture of the alimentary canal. The general aspect of the patient should be carefully noted, as this is apt to be an excellent index of the gravity of the condition. The most common causes of acute abdominal symptoms are various forms of acute intestinal obstruction, such as internal hernia, strangulation by bands, volvulus, intussusception, and so on, appendicitis, and its complications, and perforations of the alimentary tract.

**Constriction of the Ureter.**—K. W. Monsarrat divides the causes of ureteral constriction into three classes: Congenital anatomical anomalies, morbid effects of the ureteral channel itself; morbid affections which involve the ureter from the outside. Anatomical peculiarities are kinking of the duct over an abnormally situated renal vessel and an oblique or unusually high insertion of the ureter into the renal pelvis, causing difficulty in the emptying of the latter. Congenital stricture has been recorded in a few cases. The affections of the canal which may cause stricture are, ureteritis, injury, and the lesions caused by calculi. The writer declares that of the acquired conditions other than those of the canal itself, which may lead to ureteral obstruction, the most common at the upper pole is renal mobility causing kinking of the duct at the lower pole, new growths, and inflammatory processes of the pelvic organs. Obstruction to the passage of urine down the ureter will finally lead to the dilatation of the renal pelvis and of the ureter above the obstruction. In certain cases there may be resistance sufficient to lead to symptoms of ureteral colic without any marked dilatation. Diagnosis may then be difficult.

**Clavicle Fractured by Muscular Action.**—William Burns speaks of a collier twenty years old, who was running at a good pace when sharply turning around a corner he felt something at his shoulder give. Examination showed the right clavicle to be broken at the junction of its inner and middle third. There had been no fall or violence of any kind, and the fracture was due entirely to muscular action.

*Berliner klinische Wochenschrift, June 5, 1905.*

**The Principles of the Exercise Treatment in Tabes.**—Frenkel in discussing this subject says that the greatest discrimination is necessary in the application of this form of treatment, for, improperly used, it is a source of more harm than good. The mistake must not be made of confusing simple muscular exercise with the practice of coordination, and he also warns against the use of massage for tabetics. All coordinated actions must be learned by the individual, and if the power of coordination has been lost, every muscular act must be learned over again just as a child does it. The usual steps of each movement must be separately rehearsed until the ataxia is reduced sufficiently to permit the whole to be attempted. As the ataxia is due not to loss of muscular power, but to deficient sensibility, if a tabetic learns to perform a coordinated action which had become impossible, it means that the centers have become educated to get along with a subnormal degree of sensibility. In teaching a tabetic to walk, for example, a great deal of practice is needed to produce the proper coordinated movements of the trunk muscles which precede every step. As the sense of fatigue is greatly diminished, the patient's sensations are no guide as to the length of the time exercises may be kept up, and it is well to restrict them to two sessions a day each, of not more than five to fifteen minutes. The pulse rate also rises rapidly during the exercise, and it is advisable to wait after each movement until the rate has become normal again, before going on to the next exercise. The prognosis of the disease is greatly improved by the judicious employment of the principle of reduction and the author believes that the atony of the abdominal muscles and intestine, cystitis, paraplegic forms, etc., have been reduced in frequency since its introduction.

**The Diagnosis of Death by Drowning.**—Marx reviews the modern researches into this question, which though numerous, still do not render a positive opinion easy in all cases. Among the newer methods suggested is the detection of differences in the concentration of the blood in the right and left sides of the heart by determination of the freezing points, the idea being that the foreign fluid in the lungs so long as circulation continues, will be diffused into the blood of the pulmonary circulation. Attempts have been made to apply the same method to the pulmonary edema fluid, and to the cerebrospinal fluid, but without reaching very reliable results. Comparisons of the degrees of hemolysis found in the different regions of the circulation have also been made, and some authors attach importance to the manner of dissemination of the water plankton throughout the lungs. The grade of distention of the lungs or their "hyperaëration" is also considered of importance by some observers, but it appears that for forensic purposes at least it may still prove to be impossible to declare with certainty whether a body was dead or not before sinking below the surface of the water.

*Deutsche medizinische Wochenschrift, June 8, 1905.*

**The Most Favorable Time for Appendicitis Operation.**—Arnsperger, in describing the customs at Czerny's clinic in Heidelberg, says that the standpoint adopted there is against the routine, immediate operation in every case of appendicitis received. The mild, acute attacks, especially the first ones, are treated expectantly, with the idea of transferring the operation to the safer interval stage. Every case of appendicitis should come under the surgeon's care from the beginning, because special training is needed in order to judge of the gravity of the case, and because operative intervention may become necessary at any moment. Under such conditions, however, immediate operation is not always indicated, and it may be preferable to wait, knife in hand, to see if the operation may not be postponed till the attack has subsided. In other words, the effort should be made to differentiate between the severe attacks in which immediate operation is required, and the less serious ones in which delay is possible. The interval operation always offers the best chances for an uncomplicated

convalescence, and acute cases should be operated if any threatening conditions present themselves but others, if kept under constant, careful surgical supervision, may safely be treated conservatively, and held over to the interval. During the past five years the records of the clinic show 308 cases of appendicitis, with 280 operations, and a total mortality of 8.76 per cent. Of the operations, 150 were done in the interval without any deaths, 9 with complicating tuberculosis, or actinomycosis of the cecum, with two deaths, and 121 in the acute, or subacute, stage, with 25 deaths.

**A Further Contribution to the Inoculation of the Horse with Syphilis.**—Piorkowski describes further observations on the horse inoculated by him some time ago with the blood obtained from syphilitic subjects. Patients that had been treated with mercury were chosen for the purpose, with the idea that the parasites, being damaged by the drug, would give up their poison more readily. The injections were repeated every three or four days, 5-10 c.c. being given each time, and a slight rise of temperature was the only evidence of reaction. Four weeks after the first injection an eruption appeared, which spread until, at the end of eight to ten weeks, the entire body was covered with papules. There was also patchy falling out of the hair, and now, at the end of six months, some papules still persist, and a few new ones are appearing, while there is on the back a bald spot the size of a child's head. Temporary glandular enlargement was also produced. The allegation has been made that these manifestations might be the result of the injection of foreign albumin, but neither the author himself nor any of the other observers he has questioned have ever seen so pronounced an eruption from this cause. A second horse was injected with the blood of the first, and in due time developed similar lesions. Siegel has examined one of the papules, and, in serial sections, was able to find bodies which he identified with those described by him as occurring in syphilis. Similar eruptions were produced in rabbits that were injected with the blood of the syphilitic patients, or with the blood of the second horse. The author does not draw any conclusions from these observations, but hopes to throw more light on the subject by means of other experiments now in progress.

**Koch's Investigations of the Coast Fever of Cattle, and Horse Sickness in Africa.**—Kleine who accompanied Koch on the trip to Africa, which he made in order to study the cattle pests, describes some of the results obtained. It was found that the local veterinarians regarded the rinderpest as a variety of Texas fever, because of the occasional occurrence of hemoglobinuria and the presence of pear-shaped parasites in the red blood cells, but it was discovered on closer investigation that the latter appearances were simply due to a secondary infection in the course of a hitherto unrecognized disease, to which Koch gave the name of African Coast fever. The disease is characterized by high temperature, weakness, and pulmonary edema, and is fatal in 85 to 90 per cent. of the cases. In the red cells small rod, or ring-shaped, organisms are found, which in some instances are present in almost every corpuscle. Animals that survive the first attack are immune. The fact that sick animals, kept under conditions that prevent the possibility of a fresh infection, sometimes develop Texan fever, shows that the parasites of the latter must have been present in the body for some time, but only after the powers of resistance have been broken down by the first illness is multiplication of the parasites possible. All the cattle kept in infected regions finally become immune, but fresh animals at once acquire the disease. Efforts to exterminate the tic that serves as intermediary host for the disease, or to keep the cattle free from it, were found impracticable, and the best results in combating the disease were obtained by a process of immunization with the blood of infected animals, which, though still imperfect, appears to have distinct possibilities. The problem presented by the horse sickness is still more complex, as its inciting agent is undiscovered, probably owing to its minute size. Here again attempts to provide a suitable immunizing serum, though still in the experimental stage, give definite hopes of success.

*French and Italian Journals.*

**Cancerous Degeneration of the Uterine Stump After Partial Hysterectomy for Fibromata.**—Richelot has been accumulating data on this subject. Two cases have been reported by Martin. One of the patients was a woman who had been subjected to total hysterectomy, but the author thinks that at the operation a bit of the cervix was left. The second patient was a woman, fifty years old, who underwent the operation of partial hysterectomy. Ten months later the stump showed cancerous degeneration. Various other observers, Picqué, Beurnier, and Bazy, have reported the same kind of degeneration which followed partial amputation. Labeyrie has noted a case in which cancerous degeneration developed two years after the patient was operated on for fibroma. Richelot has recently been able to collect twenty-two of these cases.—*Le Bulletin Médical,* June 3, 1905.

**A Case of Angioma of the Quadriceps Extensor.**—Hardouin reports this interesting case. The patient was a man twenty-three years old, who entered the hospital for a lesion in the region of the right knee. Pain had developed about three and one-half years before. It had appeared suddenly, and was severe enough to prohibit walking for eight days. It then disappeared for some months, only to reappear from time to time. Nothing of special interest was noted in the appearance of the knee, and it was only at the end of a number of crises that a distinct swelling appeared. Inspection showed a tumor located in the lower internal parts of the quadriceps. The swelling was clearly independent of the knee, giving on palpation a sensation of elasticity. It was not very tense, and it did not fluctuate. There was a point very tender on pressure, a little above the patella near the internal condyle of the femur. The movements of flexion were limited. There was no muscular contraction or atrophy. There was a slight hydrarthrosis. The skin was intact. Diagnosis was uncertain. At operation, although an Esmarch bandage had been applied, a large quantity of blood escaped on incision. A diffuse tumor was found infiltrating all of the antero-internal part of the quadriceps. The tumor consisted of a very vascular tissue, comprising large vessels, some of which had become as large as a thumb. There were also many small vessels. The mass of muscle that had been invaded by the neoplasm was removed. The hemorrhage was arrested by means of ligatures. Examination showed the tumor to be an angioma. Recovery was uneventful.—*Bulletins et Mémoires de la Société Anatomique de Paris,* March, 1905.

**Some Points in Relation to the Technique of Appendectomy.**—Chaput presents the following conclusions: The horizontal incision, beginning near the iliac spine, avoids the section of muscular fibers, and favors drainage in all directions. When drainage has been accomplished by the abdomen, postoperative hernia can be avoided by secondary suture of the wall on the sixth day. The best treatment of the stump consists in cutting the appendix down to the level of the cecum, and suturing in layers the small resulting wound. Drainage of pelvic abscesses and of generalized peritonitis is well accomplished by rectum or by vagina. Local anesthesia is most convenient in the operation of appendectomy in the case of adults who are not nervous.—*La Presse Médicale,* June 3, 1905.

**Traumatic Delirium.**—Quénu calls attention to the existence of several kinds of delirium, post-traumatic, delirium of toxic origin, which has been noted by all surgeons, and finally a third form of delirium, which is the true delirium tremens of alcoholics. The pathogeny of the latter is not known. However Quénu is inclined to think that it is related to the phenomena of autointoxication. He does not approve of treatment by alcohol, nor by opiates. Trousseau and Vulpian also disapprove of the alcohol treatment. Vulpian administers digitalis—that is, a diuretic medication. Magnan also does not advise the use of alcohol, but prescribes the milk régime. It is for the same purpose—that is, to favor the elimination of toxins, that Quénu uses subcutaneous injections of artificial serum. Magnan uses cold enemata, and Letulle employs cold baths. Finally, in cases in which there are cardiac phenomena, Quénu prescribes small doses of the sulphate of strychnine.—*Gazette des Hôpitaux Civils et Militaires,* May 27, 1905.

**Criminal Anthropology in Forensic Practice.**—C. Antonini tells us that we are in a stage of transition from the time when criminals were all judged accountable for their crimes, and the future when all crimes will be studied in reference to the causes of their commission. We have learned the superiority of prophylactic measures over repressive measures, this knowledge stimulating us to reforms which tend to lessen the social contrasts, which are a fertile soil for the development of criminal instincts. Anthropology of criminals has formulated a great number of preventive measures, which will exercise a beneficial influence on crime. The ideas as to the responsibility of insane persons have become gradually modified, so that the popular ideas as to infanticide, political crimes, etc., has changed, and a realization has begun that we must have reformatory, as well as punitive, measures for such persons. We may divide all persons into three classes—normal, criminal, insane. The classification must be aided by all the means possible—normal psychology, criminal anthropology, clinical psychiatry—so as to give the best possible information to the administrator of the law. We must have the best medical talent, as well as the best legal talent, and a body of judges capable of comprehending the efforts to get at the real truth of the criminal's responsibility. Then we must have proper institutions for the restraint and reform of the abnormal criminal, as well as the repression of the normal one.—*Gazzetta Medica di Roma,* February 15, 1905.

# Book Reviews.

A Textbook of the Practice of Medicine.. For Students and Practitioners. By. Hobart Amory Hare, M.D., B.Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia; Physician in the Jefferson Medical College Hospital; One Time Clinical Professor of the Diseases of Children in the University of Pennsylvania; Laureate of the Royal Academy of Medicine in Belgium; of the Medical Society of London; Author of "A Textbook of Practical Therapeutics" and "A Textbook of Practical Diagnosis." Illustrated with 129 Engravings and 10 Plates in Colors and Monochrome. Philadelphia and New York: Lea Brothers & Co., 1905.

Dr. Hare needs no introduction to medical readers, his therapeutic treatises having established his reputation as a medical author of no mean rank. The present work is one that has been looked forward to with some curiosity by those who knew of its incubation, and who wondered whether the author would be as happy in his tilling of the broad field of medicine as he had been in the cultivation of the garden of therapeutics. We think it safe to assert that the book will disappoint no one. It is most comprehensive in its scope, including tropical diseases, affections of the nervous system and of the muscles, and diseases due to animal parasites. Under the latter are included the affections due to the presence of trypanosomes, but the malarial fevers are in the section treating of infectious diseases; it would seem as though they ought to be in the same section.

Dr. Hare's experience as a medical writer and editor, as well as a clinician and therapeutist has peculiarly fitted him for the task of preparing a textbook on the practice of medicine, and the book before us is such as we, knowing the author's qualifications, would expect. It is thoroughly practical in every chapter and well adapted to meet the wants of all—not too technical for the third or fourth year student and not too elementary for the practitioner. The sections on symptomatology and diagnosis are especially to be commended, but we much confess to a little disappointment in the therapeutical chapters. We had hoped that a specialist in this branch would be a little more optimistic. In the section on croupous pneumonia, for example, there is not even mention of the possibility of jugulating the disease by sodium salicylate, creosote, potassium iodide, or hot packing, although the experience of a multitude of practical men has, the reviewer believes, shown that this is possible. Even if the author of a textbook does not himself look with favor on this mode of treatment, he should at least defer so far to the authority of other competent observers as to mention their claims. There is no absolute authority in medicine, and so long as it is not a fixed science, no one who puts forth what purports to be a guide to the inexperienced is justified in keeping back any therapeutic measure which has received the stamp of approval of so many men of standing and authority. The same ignoring of alleged valuable measures is to be noted in the sections on treatment of other diseases. But, of course, no practitioner worthy of the name, depends upon a single author, and other books will supplement what is lacking in this. As a whole it is a most valuable addition to the many works on practice already before the public, and if studied in connection with other books it will be an acquisition to the library of the physician—a book to be read and studied and one full of invaluable points in pathology and symptomatology, and also, in most of the sections, in therapeutics as well.

Diagnose und Therapie des Eczems. I. Teil: Diagnose von Dr. S. Jessner, Königsberg. Würzburg, 1905.

This brochure belongs to the series of "Dermatologische Vorträge für Praktiker," of which we have reviewed a number. In some fifty pages the author undertakes the difficult task of describing (without illustration) the various forms under which eczema appears and flourishes, and of pointing out the differentiation from the many dermatoses with which eczema is so often confounded. Regional eczemas are taken up separately and discussed from a somewhat different standpoint.

Manual of Psychiatry.. By J. Rogues de Fursac, formerly Chief of Clinic at the Medical Faculty of Paris. Authorized Translation from the French by A. J. Rosanoff, M.D., Junior Assistant Physician, L. I. State Hospital, King's Park, N. Y. Edited by Joseph Collins, M.D., Professor of Diseases of the Mind and Nervous System in the New York Post-graduate Medical School, etc. New York: John Wiley & Sons; London, Chapman & Hall. 1905.

While in general the process of specialization has been conducive to the expansion and the progress of medicine, there has been a tendency at times to carry the differentiation too far, so that the subordinate division has come to be unduly separated from the main branch. Such a course must ultimately result in evil, as practice in any department of medicine will be successful only as it is based on a knowledge of the broad, fundamental principles of the entire art and science. According to this view psychiatry can be looked upon merely as a subdivision of internal medicine, with which the general practitioner should have an intelligent acquaintance, as it is he who sees the beginnings of mental aberration and to him is often afforded the opportunity of aborting the development of well-defined insanity or of diminishing the severity of the attack and of applying early the appropriate corrective and therapeutic measures. To this end books such as that before us are capable of materially contributing. The text is subdivided into two parts, namely general and special psychiatry. The former comprises in five chapters a consideration of etiology, symptomatology, and the practice of psychiatry, while the second part deals successively in seventeen short chapters with the subjects of deliria of infectious origin, psychoses of exhaustion, acute alcoholic intoxication, chronic alcoholism, chronic intoxication by the alkaloids, psychoses of autointoxication, thyrogenic psychoses, dementia præcox, chronic delirium, general paresis, mental disorders due to organic cerebral affection, psychoses of involution, manic-depressive insanity, reasoning insanity, constitutional psychopathies, the mental disorders of epilepsy, the mental disorders of hysteria, and arrests of mental development.

The book is an excellent compendium of the subjects with which it deals, and the translation is a most satisfactory one. The work can be used with advantage and profit by general practitioners and psychiatrists alike.

Diseases of the Heart.. A Clinical Textbook for the Use of Students and Practitioners of Medicine. By Edmund Henry Colbeck, B.A., M.D., B.C. (Cantab.); F.R.C.P. (Lond.); D.P.H. (Cantab.), Physician to Out-patients at the City of London Hospital for Diseases of the Chest, Victoria Park, E.; Physician to the Metropolitan Dispensary, E. C.; Late House Physician to St. Mary's Hospital, etc. Second Edition, Revised and Enlarged. Chicago: W. T. Keener & Co., 1905.

Diseases of the heart constitute a not inconsiderable field for the activities of the clinician, and the state of the circulation is a matter of no little importance to surgeon and obstetrician and specialist alike. Accordingly, each should be thoroughly equipped with the means for accurate diagnosis and ready application of appropriate remedial measures. To this end a knowledge of principles is not less essential than experience in clinical observation. Each is complemental to the other. An admirable exposition of the former is contained in the volume before us. A description of the anatomy and physiology of the heart is followed by a consideration of methods of diagnosis and a discussion of the pulse and of cardiography. A chapter is devoted to congenital affections of the heart and great vessels, and separate chapters to diseases of the pericardium and acute endocarditis and chronic endocarditis. Chronic valvular lesions are first dealt with collectively and then the states of incompetence and stenosis affecting the several valves and orifices are taken up individually. Combined valvular disease is given consideration by itself. The prognosis and the treatment of chronic valvular disease are discussed in separate chapters. The book closes with sections on disease of the myocardium, angina pectoris, and functional disorders of the heart. The text is supplemented by forty-three illustrations and a frontispiece. In the present edition a short account is given of mechanical strain of the heart and of the Stokes-Adams syndrome, and the treatment of chronic valvular disease has been amplified. Scant consideration has been given to the instrumental determination of the blood-pressure, the clinical importance of which is, however, acknowledged. Altogether the book is deserving of warm commendation.

Traitement du Cancer Utérin Inopérable. Par le Dr. J. Récamier, Ancien Interne des Hôpitaux de Paris, Ancien Aide d'Anatomie à la Faculté, Chirurgien de l'Hôpital Libre Saint-Michel. Paris: Georges Steinheil, 1905.

A work by this well-known writer on such a subject cannot fail to obtain wide attention. He arranges his material in five chapters and discusses in them the indications for the operative treatment of uterine carcinoma, giving the results of hysterectomy as well as those of palliative treatment. He considers also the various kinds of palliative treatment in the case of hemorrhage and hydrorrhea. The remaining chapters deal with the treatment of pain, of uremia, of anuria, and finally with the general treatment of cancer.

Beiträge zur Klinik der Tuberculose. Herausgegeben von Dr. Ludwig Brauer, a. o. Professor an der Universitat Marburg. Band 3, Heft 5. S. 331-426. Würzburg: A. Stuber, 1905.

The topics treated of in this publication concern the curability of tuberculosis, the diagnosis of cavities and nervous deafness occurring in the course of the disease. All are discussed with characteristic Teutonic exhaustiveness.

# Society Reports.

## AMERICAN NEUROLOGICAL ASSOCIATION.

*Thirty-First Annual Meeting, Held at Philadelphia, Pa., June 1, 2, and 3, 1905.*

(Special Report to the MEDICAL RECORD.)

THE PRESIDENT, DR. WILLIAM G. SPILLER OF PHILADELPHIA, IN THE CHAIR.

FIRST DAY—THURSDAY, JUNE 1.

**President's Address.**—Dr. WILLIAM G. SPILLER of Philadelphia, in this address, said that disturbances in the associated movements of the eyes (Blicklähmung of the Germans) afford a sign of localizing value in lesions of the brain, and yet this subject has received comparatively little attention. He had had an opportunity to study four cases in which paralysis of lateral associated ocular movements occurred, and nine cases in which paralysis of upward or downward associated ocular movements was a striking sign, including three of the four cases referred to above. He had examined microscopically the material obtained from four of these cases. His remarks were devoted chiefly to the upward and downward associated palsies. Paralysis of lateral associated ocular movements was indicative of a lesion of the posterior longitudinal bundle near the sixth nucleus. The evidence that could be obtained regarding the existence of a cortical center for associated movements related almost entirely to lateral associated movements and paralysis of this form when resulting from a cortical lesion was transitory. He had little anatomical or pathological evidence that was really valuable concerning the existence of a cortical center for upward or downward associated movements, but in reasoning from analogy we must assume that such a center, or centers, existed. All the pathological evidence that Dr. Spiller had been able to obtain in cases of persistent palsy of associated upward or downward movement was indicative of a lesion near the aqueduct of Sylvius. It was extremely doubtful whether a lesion confined to the corpora quadrigemina and causing no pressure on the surrounding parts, ever caused paralysis of the associated ocular movements. Topolansky had shown that electrical irritation of the corpora quadrigemina of rabbits did not produce ocular movements and that this process could be removed without producing symptoms; and Bernheimer, from experiments upon monkeys, had demonstrated that the ocular movements did not depend upon the integrity of the corpora quadrigemina, that this part of the brain did not contain a reflex center for these movements, and that after destruction of this part the ocular movements were normal. Cases had been reported in which the corpora quadrigemina had been destroyed in a man without disturbance in the movements of the eyeballs. The ocular motor nucleus, as shown by recent investigations, was merely the place for the transference of impulses, and, according to Siemerling, we were not in a position to state which parts were concerned in the innervation of the individual muscles. In two of the cases that Dr. Spiller had studied, paralysis of upward associated movement was caused by a tumor within the pons. In neither case was the oculomotor nucleus directly invaded, although undoubtedly compressed in each. Three other cases of his series afforded evidence against a center for coordinated ocular movements in the corpora quadrigemina. In one the paralysis at first was only in upward movements, later in lateral associated and in downward associated ocular movements. In these cases, therefore, a paralysis at first confined to one form of associated movements later extended to other forms. In any case, the paralysis of associated ocular movements disappeared, leaving only paresis of the left superior rectus, and finally this also disappeared. In still another case, the associated palsy disappeared, leaving paralysis of muscles only on one side. It was very common to have a palsy of one or more branches of the oculomotor nerve in association with paralysis of associated upward or downward movement, and this was more easily explained by a lesion of the oculomotor nucleus than by a cortical lesion. Cortical centers controlled associated movements in isolated muscles. The lateral associated ocular movements could be explained by the connection formed by the posterior longitudinal bundle between the nucleus of the branch and the internal rectus muscle and the nucleus of the sixth nerve of the opposite side. It was reasonable to suppose that certain fibers connecting different parts of the oculomotor nucleus with one another or connecting the group of nerve cells innervating the inferior rectus with the nucleus of the trochlear nerve had a coordinating function similar to that of the posterior longitudinal bundle, and that this function might be disturbed by a small lesion. It was striking that the paralysis of downward associated movement, necessitating the implication of two separate nuclei of ocular muscles without paralysis of upward associated movement was exceedingly rare, far more so than was the isolated paralysis of upward associated movement. Dr. Spiller said he had studied thirty-eight cases of paralysis of upward or downward associated movements reported in the literature, and these, together with his own nine cases, made a series of forty-seven. He had found paralysis of associated upward movement without paralysis of downward associated movement in twenty-six cases. Paralysis of upward associated movement with paralysis of downward associated movement was found in sixteen cases. Paralysis of upward associated movement with impairment of lateral movement often developing later was found in fifteen cases. Paralysis of upward associated movement without impairment of lateral movement was found in twenty-two cases. Paralysis of downward associated movement without paralysis of upward associated movement was found in five cases. The reaction of the iris was impaired in fourteen cases. The optic nerve was affected in fifteen cases and normal in twelve cases. Convergence was impaired in fifteen cases. Ptosis was found in seven cases and was absent in thirteen cases. An autopsy was obtained in nineteen cases. In all of these cases, except one, parts about the aqueduct of Sylvius were implicated. Tumor was found in fourteen cases, bullet wound in one case, apoplectic cyst in one case, hemorrhage in one case, and an uncertain lesion in one case. Recovery, or partial recovery, occurred in seven cases. As a result of his studies, Dr. Spiller believed that persisting paralysis of associated lateral movement indicated a lesion of the posterior longitudinal bundle; that persistent paralysis of associated upward or downward movement indicated a lesion in the vicinity of the oculomotor nucleus, and that paralysis of associated ocular movement was not the result of a lesion of extracerebral nerve fibers. Lesions of the cerebral cortex might certainly cause paralysis of lateral associated movements, and possibly of upward or downward associated ocular movements, but cortical paralysis of associated ocular movements was transitory, except possibly when the center on each side of the brain was destroyed. Paralysis of associated ocular movements might be caused by hysteria. Any case in which associated ocular palsy was persistent and was of organic nature was unsuitable for operation unless the operation was merely palliative. The paralysis of associated ocular muscles might be produced by inflammatory lesions, or lesions of a similar character (alcohol, syphilis), as well as by tumor, and might disappear later in the course of the disease.

**A Fatal Case of Neurasthenia.**—Dr. THEODORE DILLER of Pittsburg reported the case of a man of excellent habits who, at the age of 46, after twenty-five years of incessant activity, became profoundly neurasthenic, with many morbid fears. Repeated examinations of his organs and secretions by various observers failed to discover organic disease. The patient died of collapse at the age of 49, having exhibited a few weeks before his death some loss of power in his legs, and occasionally loss of control of the bladder.

No autopsy was held. Although admitting that organic disease might have been present which escaped his notice, Dr. Diller inclined to the tentative opinion that the patient died of a progressive loss of vital tone, which had produced the clinical picture of neurasthenia. He mentionad a second case, accounted one of neurasthenia, in which the vital tone for a time was so low that death was feared, but in which recovery subsequently ensued.

Dr. B. Sachs of New York thought the title of Dr. Diller's paper was unfortunate, and that one could not admit such a thing as a fatal case of neurasthenia, especially when no autopsy had been made. There were many other possibilities in this case.

Dr. George W. Jacoby of New York said that Diller's case was of great interest, but that the American Neurological Society should not go on record as accepting a diagnosis of neurasthenia without an autopsy having been made. There were many cases of marasmus in which the cause of the symptoms could not be found at autopsy. There was a class of cases in which there was clinically nothing but marasmic symptoms to be found in which there was nothing positive except absence of free hydrochloric acid. The other gastric secretions and the blood were negative. Did such lesions cause death? Grawitz had reported many fatal cases due to such cause. We should be careful in our clinical examination in order to exclude other diseases. This case proved that all patients should be examined in every possible way in case there was doubt as to the diagnosis.

Dr. Langdon said that he agreed with Sachs and Jacoby in reference to this case, which should be put down as one of incomplete diagnosis. He had had such cases, which he called prepernicious anemia. If the patients had died in that stage, the disease would have been put down as hysteria or neurasthenia, but there was later well-marked pernicious anemia. He did not admit the diagnosis which Diller had made.

Dr. Joseph Collins of New York said that he hesitated to discuss this case, because it raised the question of diagnosis. He said it would be a stigma of impotence to let this diagnosis go unchallenged. He had never heard a better description of arteriosclerosis than was set forth in Diller's paper. The autopsy, he believed, would have shown contracted kidney, hardened blood-vessels, and other lesions of arteriosclerosis.

Dr. Philip C. Knapp of Boston said the diagnosis should not be attempted on this evidence.

Dr. Meyer believed the diagnosis was wrong, but thought the error not so serious as the previous speakers contended.

Dr. H. C. Gordinier of Albany suggested the diagnosis of aplastic anemia.

Dr. F. X. Dercum of Philadelphia said one must be careful regarding the term neurasthenia. He made a diagnosis of something else unless he was certain of neurasthenia.

Dr Diller, in closing, said that he was obliged for the individual views expressed. He thought the diagnosis correct. He had been careful not to say that there was not some organic disease which produced the neurasthenia yet escaped his observation. He had excluded phthisis, Bright's disease, and arteriosclerosis. Should he reverse his diagnosis after death, it would be because neurasthenia could not result fatally.

**A Study of Pathological Gait.**—Dr. Joseph Sailer of Philadelphia presented this paper, which gave the results of several years' study. In studying the gait his method was to take a strip of ordinary manila wrapping paper, 15 by 20 feet long, and fasten it upon the floor. The soles of the feet of the person to be studied were covered with a black paint made of lampblack and linseed oil, and he was directed to walk the full length of the paper. The impression of the feet was thus obtained. The paint was made somewhat thicker than ordinary paint, and was evenly smeared on with cotton. Sailer exhibited a number of such impressions, four years old, which were as good as when first made. Sailer thought this gave better results than any other method, and was at the same time very simple and easily carried out. By this plan, the length of the steps, the separation of the legs, the contact of the foot, the dorsal flexion of the toes, rotation of the leg, force with which the foot was brought to the floor, and other features could be accurately studied. It did not give an idea of the action of the limbs while in the air, but this could be studied by instantaneous photography. There were two groups of pathological gait; first that due to disturbance of the bones; second, that due to disturbance of the neuromuscular mechanism.

**Multiple Sclerosis; Four Cases, with Autopsy; Consideration of Differential Diagnosis.**—Dr. E. W. Taylor of Boston read this paper. He stated that multiple sclerosis had received very little attention in this country, only seven cases having been reported in America. He said that a study of recent literature indicated that not enough pains had been taken to differentiate this disease from others, and he believed the disease was much more frequent in this country than would appear from autopsy records. It was very frequently reported from the clinic of Oppenheim and others of Europe. The disease must be differentiated from as many as twenty-three other diseases. The author reported four cases with autopsy, and in addition had three cases now under observation as well as five or six other cases which further study would probably show to be multiple sclerosis. All four of the cases reported were in women, two of whom were above 40 years of age. In three there was complete absence of the three cardinal symptoms—intention tremor, nystagmus, and scanning speech. The pathological anatomy was clean cut, definite, and unmistakable, more so than in any other disease. He found that there was no choice between gray and white matter, so far as distribution of the lesion was concerned. Systemic distribution was rare. It was not necessarily distributed throughout the brain and the cord. Taylor considered it primarily a myeline degeneration, and not a primary gliosis. He found actual patches of sclerosis in the dorsal roots. He had observed patches of sclerosis absolutely separate from the blood-vessels. He thought more attention should be given to the study of the eye symptoms. As indicating the difficulty in diagnosis, the author said that his first case was mistaken for one of hysteria, the second for brain tumor and the third for diffuse combined degeneration, and that the correct diagnosis was made only in the fourth case, and then shortly before death. In all the cases the lesions of multiple sclerosis were found, though in the third case the lesions were somewhat limited and only in the cord.

Dr. B. Sachs of New York said that he had been on the lookout for multiple sclerosis for several years in a large neurological service. By exercising every care, out of 150 cases of nervous disease he had been able to make a diagnosis of seven cases of multiple sclerosis; two of these patients had died, but autopsies could not be obtained. Some cases labeled ataxic paraplegia turned out later to be multiple sclerosis. He would question whether it was warrantable to draw a sharp line between combined degeneration and multiple sclerosis. He thought one disease might merge into the other. He agreed with Taylor that examination of the eye-ground was important. He also thought, as did Strümpel, that we should drop the term intention tremor and substitute for it ataxic tremor. He had observed tremor of the head when examining for nystagmus. Multiple sclerosis was hard to differentiate from cerebrospinal syphilis.

Dr. Joseph Collins of New York said that at the Montefiore Home, where only incurable cases were taken, he had made a careful examination of all the patients for multiple sclerosis. In 135 cases of nervous disease he found only two that had been called multiple sclerosis. On reexamination he found only seven cases which he could by any possibility call multiple sclerosis. In a service of eight years in the New York Hospital, with 200 beds in his care, to which

many cases of nervous disease were admitted, he had made the diagnosis of multiple sclerosis in only five cases. He agreed with Dr. Taylor upon the importance of the eye symptoms. In one case at autopsy he found patches of sclerosis scattered throughout all the internal organs as well as in the cord. Whether this widely disseminated sclerosis was all of the same character and origin, he was unable to to say, but considered it a valuable observation.

Dr. B. Onuf of Sonyea, N. Y., observed in cases of multiple sclerosis spasmodic movements of the extremities and spasmodic laughter. In one of his cases, when the patient attempted to talk, before he proceeded far he would break out into a fit of uncontrollable laughter. This would be repeated a number of times.

Dr. J. K. Mitchell of Philadelphia had gone over 1,000 general neurological cases at the Orthopedic Hospital and Infirmary for Nervous Diseases and elsewhere, in the last two years, and had seen only four cases in which he would diagnose a multiple sclerosis. The difficulty of making a positive diagnosis without the cardinal symptoms was great.

Dr. H. M. Hoppe of Cincinnati said that multiple sclerosis should not be mistaken for hysteria, because in hysteria there was no ankle clonus, Babinski's sign, or other positive evidence of organic disease. During the past 11 years in about 400 cases of nervous disease, he had had only one case of multiple sclerosis, which was confirmed at autopsy. The symptoms of multiple sclerosis were evanescent. He questioned whether it was a primary myeline degeneration.

Dr. Taylor, in closing, said that he accounted for the larger percentage of cases of multiple sclerosis abroad by the fact that, where in this country we would put down the diagnosis as blank, abroad, either by more careful study or otherwise, they settled upon a diagnosis. He did not agree with Sachs that there was no sharp line between ataxic paraplegia and multiple sclerosis, but agreed as to the difficulty of differentiating the latter disease from cerebrospinal syphilis.

**Two Cases of Cervical Rib, with Operation.**—Dr. Hugh T. Patrick of Chicago presented this paper. He said that when he came to look up the literature he found that cases of cervical rib with operation were very rare. In his cases the symptoms were those of sensory disturbance referred to the distribution of the lower part of the brachial plexus. Both cases were in young women. In one the condition was bilateral and was peculiar in that no symptoms were shown on the side of the larger rib. Both patients had been to prominent neurologists who failed to make a proper diagnosis, which he arrived at by means of the *x*-ray. The operation was followed by anesthesia and pain due to operative disturbance of the plexus, but this was only temporary.

Dr. M. Allen Starr of New York had had one case this year of bilateral cervical rib. The symptoms were worse on the side of the larger rib.

Dr. Wolfstein reported a case of cervical rib which was at first mistaken for uniradicular palsy.

Dr. Harvey Cushing of Baltimore said that one important feature from the surgical aspect was that the rudimentary rib might be cartilaginous, as he found in one case. He removed a cervical rib a few years ago, but in this case there was no return of motility or sensation in the parts affected.

Dr. D. J. McCarthy of Philadelphia reported a case from the Phipps Institute.

Dr. Patrick, in closing, said that he considered diagnosis by palpation uncertain, and that it was impossible to make a diagnosis without the *x*-ray which rendered it extremely easy.

**Acute Polioencephalitis Superior (Wernicke).**—Dr. J. Ramsay Hunt of New York read this paper, stating that acute polioencephalitis superior was an encephalitis with a hemorrhagic tendency which involved also the white matter and the basal ganglia. In some cases the white matter was more involved than the grey. He reported a case in a man aged 40, who had been addicted to excessive alcoholism for many years. The onset of the disease was sudden and manifested by headache, vomiting, and profound prostration. There was paralysis of all the ocular muscles except the external recti, and the intrinsic muscles. Later, there was difficulty in swallowing, bradycardia, delirium, great motor restlessness, and incontinence of urine and feces. Finally coma developed, and death resulted from respiratory failure. The duration of the illness was five days. The autopsy revealed foci of encephalitis in the medulla, and pons, also internal hemorrhagic pachymeningitis.

Dr. George W. Jacoby of New York reported the case of a physician 33 years of age. He had complete ophthalmoplegia. Upon attempts at movement of the eyes the patient would break out into a fit of uncontrollable laughter. The speaker thought that in this case there was involvement of the optic thalamus. He had slowly improved. The ophthalmoplegia and fits of laughter had disappeared.

Dr. Theodore Diller of Pittsburg spoke of a case of internal hydrocephalus of one and one-half years' standing, finally confirmed by autopsy, which was mistaken at first for encephalitis.

Dr. E. W. Taylor of Boston said that attempts at determining the exact extent of the lesion of the brain at autopsy were often not entirely successful; because of the difficulty of making out the artificial distinction of the various anatomical parts of the brain.

Dr. Hugh T. Patrick spoke of a case in which there was facial paralysis with involvement of the neck muscles, which was found to be simple poliomyelitis in the cord and polioencephalitis in the brain, the white matter not being involved.

**Disease of the Cerebral Venous System.**—Dr. D. J. Mc Carthy of Philadelphia presented this paper in which he reported a study of the brain in 23 cases of generalized arteriosclerosis. Preparatory to this he studied the vascular supply of 120 brains at the Phipps Institute. He found no regularity in the venous supply to the cortex, but the arterial supply was more uniform. It was important to recognize the unity of the vascular system of the brain. There was too much tendency to study the arteries to the exclusion of the veins and capillaries. In one of his 23 cases he found a gelatinous exudate in the ventricles. This was rare. It might be a transudate due to passive congestion. Arterial and venous hemorrhage was differentiated by microscopical examination. Free venous hemorrhage occurred more frequently in infancy and was the result of trauma.

Dr. George L. Walton of Boston spoke of a case which was at first thought to be arterial hemorrhage, but proved on autopsy to be escape of blood from the lateral sinus. It was in a young man, and resulted from a blow on the jaw received in a friendly boxing bout. He thought the force, instead of being distributed, as it usually is, throughout the petrous portion of the temporal bone and finally around the cranium, was in this case transmitted directly through the bone, which was broken, and expended upon the lateral sinus.

**A Study of Two Brain Tumors of Endothelial Origin—One a Multiple Cylindroma, One a Neuroepithelioma.**—Drs. Herman C. Gordinier and H. H. Carey of Albany read this paper, in which they gave a detailed report of the symptoms and the pathological findings, with special attention to histological structure of the tumors. Both tumors were incorrectly located *intra vitam*. The first case was one of multiple cylindroma, which involved the second, third, fourth, and eighth cranial nerves, and produced symptoms very much like those of tumor of the corpora quadrigemina. The tumors were of a hyaline-like material; the basement substance was much in excess of the cellular element. The nuclei varied in size. Origin from the pia mater or cerebral cortex could not be made out. The authors considered the tumor congenital in origin, and thought that the cells were destined originally to form blood-vessels on account of the tendency to do so in the tumor. The malignancy of the tumor was not great. The

second case was that of a boy, 10 years old. The tumor was a neuroepithelioma of the choroid plexus of the fourth ventricle growing dorsally and producing symptoms of a tumor of the cerebellum by involving the median lobe. The patient suffered from headache and dizziness, much disturbance of gait and double optic neuritis. The cerebellar tissue was not involved. The authors thought that the tumor had its origin in the ependyma of the fourth ventricle.

*(To be continued.)*

## AMERICAN GYNECOLOGICAL SOCIETY.

*Thirtieth Annual Meeting Held at Niagara Falls, May 25, 26, and 27, 1905.*

DR. EMILIUS C. DUDLEY, OF CHICAGO, PRESIDENT.

*(Continued from page 991, Vol. 67.)*

**The Relation of the Appendix to Pelvic Disease.**—Dr. REUBEN PETERSON of Ann Arbor, Michigan, read a paper on this subject, in which he presented the following conclusions based upon the clinical and microscopical study of 85 appendices removed during the course of operations for pelvic disease. In the first series of 200 cases, reported last year by him, a little over 50 per cent. of the appendices were found microscopically to be normal. In the present series, 49.3 per cent., or practically 50 per cent., were found normal. The same microscopical classification was adopted as last year, namely, (1) negative; (2) chronic inflammation; (3) doubtful significance; (4) former inflammation; (5) acute inflammation, and (6) periappendicular inflammation. The only change in the classification was that groups 1 and 3 were practically united, and with the exception of two cases were placed in the negative group. This was a minor detail of classification, however, as in each series the appendices in both groups were considered normal. 2. In both series practically one-half of the removed appendices were microscopically normal, while the remainder showed evidences of acute or chronic inflammation, or the results of former inflammation. 3. The average length of 79 appendices was 9.99 centimeters. In the first series the average length was 8.25 centimeters. 4. The appendix was found adherent in 20 out of the 85 cases, or in 23.4 per cent. This was 5 per cent. higher than in the last year's series. But both series show that the appendix was adherent twice as frequently in those cases where microscopic examination showed past or present disease. A certain proportion of adherent appendices were, however, perfectly normal microscopically. 5. Abnormalities in shape were noted in 27 out of 85 cases. The appendices were found to be club-shaped, constricted, or bent upon themselves in 10 of the 27 cases, yet microscopically such appendices were normal. Hence the same conclusions arrived at last year held good for the present series: Mere shape of the appendix cannot serve as an index of its normality or disease. Appendices may be club-shaped, constricted, or bent upon themselves, and yet be perfectly normal. 6. There were fecal concretions noted in 14 out of the 85 cases. This gave a percentage of 16.4, and was double that noted last year. This might be explained by the more accurate observations made in the present series of cases. It did not take into consideration microscopic concretions, but only the palpable forms. In 7, or one-half the cases, the appendices with fecal concretions were normal, hence, as noted in the first series, their existence did not denote disease. 7. Exactly 50 per cent. of the 34 patients in the present series with chronic disease of the appendages, showed accompanying disease of the appendix. 8. The following conclusion would hold good for both series: In chronic disease of the appendages adhesions of the accompanying appendices are present in nearly 50 per cent. (47 per cent., second series) of the cases where microscopic examination shows the latter to be diseased. In a certain proportion of cases, however, although the appendix may be adherent, it is also perfectly normal. 9. Of the 17 normal appendices accompanying chronic disease of the appendages, 9 were noted as changed in shape, or contained fecal concretions, hence in chronic disease of the appendages, the appendix, which is club-shaped, constricted, or contains fecal concretions, is not necessarily diseased. 10. There were 21 cases of uterine fibromata among the 85 patients. Of these, 48 per cent. had accompanying disease or evidence of former disease of the appendix. The percentage was in the first series practically the same. 11. There were eight cases of large ovarian cystomata in the second series. Of these, 50 per cent. had accompanying disease of the appendix, 20 per cent. less than in the first series.

**Inflammatory Conditions of the Appendix Accidentally Brought to Light in Pelvic Operations.**—Dr. HUNTER ROBB of Cleveland, Ohio, stated, in a paper on this subject, that of 370 appendices removed and examined microscopically, 103 were normal; 46 showed signs of a chronic, and one of an acute, appendicitis. In 88 cases there was an hypertrophy of the subperitoneal or internal coat, or of both coats. In 66 cases the changes were of doubtful significance; in 36 the lumen was occluded; in 16 dilated; in 12 the appendix contained concretions; in 1 case the appendix was cystic and had undergone myxomatous degeneration; in 1 case no lymphoid tissue was present. Conclusions: "(1) In a large number (in his series, 323 out of 370) of pelvic cases no inflammatory changes in the appendix were found even microscopically. (2) When one finds a normal appendix in conjunction with disease of the pelvic organs, it is improbable that the latter condition has been brought about by a perforation of the appendix which had afterwards healed. (3) On the other hand, an old periappendicitis and adhesions might often be looked upon as the result of a septic infection, originating in and spreading from the organs of generation. (4) An appendix which looks abnormal macroscopically does not always show inflammatory changes on microscopical examination. (5) Nevertheless, when the removal of the appendix adds very little to the gravity of the abdominal operation, for the benefit of the patient it should be taken away. (6) In his series of 370 cases there were four deaths; but a careful analysis shows that the fatalities should in no instance be attributed to the removal of the appendix."

**Appendicitis in Its Relation to Pregnancy.**—Dr. HENRY C. COE of New York stated that his experience had led him to believe that many mild cases were overlooked, or were mistaken for other affections—adnexal disease, pyelitis, colitis, etc. In view of the tendency to obstinate constipation and intestinal toxemia, one would expect to find that appendical complication were not infrequent during pregnancy. Moreover, many women with a history of former attacks became pregnant, when all the conditions favored recurrences, though they were usually of a mild type. Eight illustrative cases were cited from the writer's private practice, four patients recovering without operation, two being operated upon at the third and fifth months, without interruption of the pregnancy, while the remaining two were carried through the puerperium and submitted to operation later. Dr. Coe then discussed the symptoms, diagnosis, differential diagnosis, prognosis, and treatment. The writer's views coincided practically with those of Pinard, namely, to treat appendicitis in the pregnant female according to the same rules as in the non-pregnant. In mild cases carry the patient to term, if possible, and operate as soon as convenient after the puerperium, if the trouble persisted. With the persistence of local pain, and if an induration was felt, operate as in any other case. Perforation and abscess formation called for immediate operation, rapid work, as little handling of the uterus as possible, and free drainage. Accouchement forcé, previous to operation, as recommended by Marx, was not approved by the writer. Since the toxemia of pregnancy was often of intestinal origin, as in appendicitis, careful attention should be paid to the regulation of the bowels by the use of laxatives, high enemata, restricted diet, the drinking of large quantities of water, etc.

DR. A. LAPTHORNE SMITH of Montreal said that no

machine was stronger than its weakest part, and in the human mechanism the weakest part was the one which was the least used. Owing to our mode of living the vermiform appendix was one of the least used organs, and consequently the weakest. In all cases of pelvic disease, and in most cases of pregnancy in cities, the whole organism was weakened and labored under difficulties. There was, therefore, in such cases a special reason why an organ, which even in man was unable to withstand the attacks of bacteria, should be unusually liable to infection, ulceration, and gangrene. In many cases of supposed pelvic disease, and fever after delivery, the appendix was responsible for most of the trouble, although it might not always present gross lesions. Therefore, no woman should be allowed to begin or continue a pregnancy with an appendix which was known to be chronically inflamed, and all operations for the removal of the uterine appendages should begin by the removal of the vermiform appendix.

Dr. Seth C. Gordon said it was his invariable rule, whenever he opened the abdomen for any other purpose, to remove the appendix whether good, bad, or indifferent.

Dr. Frederick W. Sears stated that one should not be fearful about operating upon pregant women for appendicitis, as his experience had been that they bore the operation better than the non-pregnant. His experience, however, had been limited to three cases.

Dr. Andrew F. Currier did not believe that it was good surgery to remove any organ of the body which he was not convinced was diseasel. In certain cases in which there was a strong probability of malignant disease, an exception could be made; but the function of the surgeon was to build up rather than to remove.

Dr. Clement Cleveland looked upon the appendix as a useless organ, and when operating for other intraabdominal conditions he would not hesitate to remove the appendix. In cases where the appendix had not been found diseased, but had been removed, there was no history to show that any harm had come to those patients. The effect had been *nil*. The arguments of Dr. Currier did not appeal to him.

Dr. Fernand Henrotin said that so far as clinical observation was concerned, the appendix was not only responsible for inflammatory attacks, but for a good deal of indigestion, colic, dyspeptic symptoms, and trouble in the abdomen which was never accurately diagnosed. After an operation for its removal patients were less affected. He would remove the appendix in every instance when operating for some other purpose, unless there were contraindications to its removal.

Dr. Herman J. Boldt said that quite recently a woman, pregnant about the fourth month, had a number of attacks of acute pain in the abdomen. Upon bimanual examination under ether, it was impossible to determine anything definite, but because of the extreme pain he opened the abdomen and found an appendix about six inches long, curled upon itself, and in a state of acute inflammation. Since its removal the woman had been well. He narrated other similar instances.

Dr. James F. Baldwin of Columbus, Ohio, had for the last eight years made it a routine practice to examine the appendix in all cases when operating for other intraabdominal pathological conditions, and had removed the appendix in a large number of cases. Out of 3,000 abdominal sections he had removed the appendix 1,800 times.

Dr. E. P. Davis said there were special reasons why appendicitis should appear in pregnant women, and why the appendix should be removed during pregnancy. As a general proposition, the bacillus coli communis was present in abundance in the intestine of every pregnant woman, and any condition of the intestinal tract during pregnancy, which in the slightest degree lessened peristalsis of the normal intestine, predisposed to infection by that organism—infection of the adnexa, the uterus, or the appendix. On the other hand, a pregnant woman, whose metabolism was well maintained, was in good condition for a surgical procedure, because she had a physiological blood plethora. She bore anesthesia well. The removal of the appendix was applicable to pregnant women and need not be delayed until after delivery, as it was much safer to do the operation during pregnancy than to let the woman run any risk.

Dr. Arthur W. Johnstone said that his experience had been limited to four operations performed on pregnant women for appendicitis between two and a half and four months. All recovered. There were no miscarriages.

Dr. Malcolm McLean had not arrived at the point where he would remove an organ simply because it might in the future give trouble. He advanced reasons for taking this stand.

Dr. Ely Van de Warker saw no reason why, if one saw a perfectly healthy appendix, and the abdomen was opened for some other purpose, it should be removed for fear that something was going to happen to it in the future. Such a proposition seemed to him too absurd to discuss. Appendicitis was comparatively rare, in his opinion. He had spent his life in doing gynecological work, and had opened the abdomen thousands of times, but had never removed a normal appendix, yet he had seen no harm ensue from leaving it. If one were to follow such reasoning, he might as well remove the gall-bladder and other organs for fear they would cause trouble in the future.

Dr. J. Riddle Goffe did not believe in removing a healthy organ, such as the appendix, when we did not know what its function was. It might have some function. There was a time when physicians did not know the function of the spleen, but it was not removed because the abdominal cavity was opened. There was a time when we did not know the function of the thyroid gland, but surgeons did not take it out. He thought we might wake up to the fact some day that the appendix had a function.

Dr. Philander A. Harris raised his voice very strongly against removing perfectly healthy appendices unless there was abundant time to do it, or unless the patients desired it.

Dr. H. J. Lipes of Albany said the appendix had a decided function. It was composed largely of mucous glands, situated in the lower part of the cecum, and there was no more stagnant portion of the intestinal tract than it, and no portion that needed lubrication more to get rid of the fecal material. He thought this mucous secretion helped along the digestion.

**The Radical Abdominal Operation Versus the Vaginal Operation for Carcinoma of the Uterus.**—Dr. C. C. Frederick of Buffalo, N. Y., read a paper on this subject, in which he drew the following conclusions: "(1) The radical operation for carcinoma of the uterus should be done only when the gross lesions can quite certainly be diagnosed as confined to the uterine tissue. (2) The deeper tissues of the cervix were generally invaded first, and also the deeper layers of the vagina in the immediate vicinity of the cervix were infected before the disease appeared upon the mucous surface. (3) The bladder wall was very early infected, especially when the anterior lip of the cervix was the starting-point of the growth. (4) When pain became a prominent symptom, the growth had passed beyond the uterine tissue. Such an involvement was a positive contraindication to a radical operation. (5) Carcinoma of the body presented an entirely different condition. In these the liability of extrauterine lymphatic infection was less for the same period of growth. (6) When the radical operation was done, it was necessary to remove as much of the vaginal walls and pericervical tissues and broad ligaments as possible. (7) It was a well-attested fact that in most recurrences after hysterectomy the growth was found in the cicatrix and the adjacent vaginal tissues. (8) In view of the point at which recurrence began, removal of the pelvic lymphatics and glands did not insure against recurrence. (9) If the vagina was ordinarily capacious, and if the uterus could be drawn down, it would seem that the vaginal route was naturally the one by which the operation could be most readily and thoroughly done. (10) It was possible, yes, probable, that some cases of recurrence were due to the

infection of the freshly incised tissues at the time of operation by contact of the carcinomatous mass or its fluids. By the vaginal operation this might to a degree be prevented by the removal of the cancerous mass or by thoroughly cauterizing it before beginning the operation proper. (11) The operation could be more quickly done than by the abdominal route. (12) Convalescence after vaginal operations, was much more rapid; there was much less pain, and there was much less shock to the nervous system. (13) For the cervical carcinoma, in most instances the combined clamp and cautery operation seemed to be the preferable one. (14) Undoubtedly, infected areas were reached and rendered harmless by the free use of the cautery in this operation. (15) The vaginal walls and all tissues should be seared by it, except those at the utero-vesical junction." The writer would, therefore, limit the abdominal operation to those patients in whom the condition of the vagina or immobility of the uterus made the vaginal operation practically impossible.

**Paravaginal or Abdominal Operation in Carcinoma of the Uterus.**—Dr. GEORGE GELLHORN of St. Louis, Missouri, in a paper with this title, presented the following conclusions: (1) The object of the symposium was to discuss how we might improve our operative technique in order to better the results in uterine cancer. (2) The following conclusions applied only to cancer of the cervic uteri. (3) The radical abdominal operation, so far as the routine ablation of the lymphatic organs of the pelvis was concerned, had thus far failed to yield the desired results. (4) On the other hand, the eradication of the parametria had been found to reduce greatly the percentage of cures. (5) The single abdominal and vaginal operations which did not include this procedure should be discarded. (6) For the extirpation of the parametria, Wertheim's method was the best of the abdominal operations. It had, however, he believed, certain disadvantages as compared with the paravaginal method of Schuchardt. (8) Considering the encouraging results of igni-extirpation, a combination of thermocautery with paravaginal extirpation gave promise of further improvement in operative results.

**A Suggestion for the Surgical Treatment of Incontinence of Urine in Women.**—This was the title of the president's address, delivered by Dr. E. C. Dudley of Chicago. After referring to the expansion of gynecology, he suggested an operation which was based on the same principle as that proposed by Albarran, namely, advancement of the meatus urinarius to the clitoris, but this was done without dissecting the urethra free and, therefore, it obviated the danger of sloughing of the urethra; it was performed as follows, in two steps:

"*First Step.*—A horse shoe-shaped surface is rather deeply denuded between the meatus urinarius and the clitoris, and to either side of the urethra throughout the entire length of it.

"*Second Step.*—The meatus is drawn up to a point near the clitoris, and is secured there by means of two sutures. The lateral portions of the denuded surface are now closed. The effect of the operation is to replace and to retain in its functional relations the sagging displaced urethra. The two purse sutures necessarily stretch the urethra upward to the region of the clitoris, and the lateral sutures must tend to hold it in its new position. By this means, it is proposed to straighten out the urethrocele by longitudinal traction, and by lateral traction to collapse and to hold together the dilated walls of the urethra, and thus to overcome the sacculation at the neck of the bladdder, where residual urine is apt to accumulate and give rise to trigonitis cystitis, and possible incontinence. In many cases, it will be necessary to combine with the operation some appropriate surgical treatment for an associated cystocele, and in nearly all cases to perform perinerrohaphy to relieve also relaxation of the posterior vaginal outlets."

In one case he saw fit to narrow the pouching urethra in order to overcome the urethral dilatation. He had performed this operation five times since January 1st, 1905. In the first four cases relief from incontinence was immediate and had been continuous. The last operation was too recent to be taken into account. In one case there was so much relaxation of the skin and other soft parts in the region of the clitoris that he feared the sutured urethra might pull these structures down to the old malposition instead of being held up by them, but so far it remained well in place. In such a case, again, or in the event of recurrence from such a cause, he should be disposed to make a deep oval denudation over the pubes on the mons veneris, just above the clitoris, the longer axis of the oval being directed transversely, and to unite the margins of this wound by a transverse line of union, so as to make the clitoris a fixed point on a sufficiently high plane to hold the urethra taut. For obvious reasons, this procedure would be preferable to the removal of the clitoris, and the union of the meatus to the parts thereby exposed.

**The Mortality in Operations for Fibroid Tumors of the Uterus.**—Dr. J. MONTGOMERY BALDY of Philadelphia contributed a paper on this subject. Degenerations of fibroid uterus, except malignant and necrotic, were of more scientific interest than practical value. The greatest dangers of fibroids lay in the large death-rate following operations due to heart degeneration, arterial changes, lung thrombosis, etc. He pointed out the condition inherent in all fibroid tumors of the uterus, and said the tumor should be removed at a period early enough to anticipate the changes.

**Migratory Uterine Fibroids.**—Dr. REUBEN PETERSON of Ann Arbor, Michigan, reported cases showing the different stages of the separation of the uterine growths from the uterus, and their attachments to other abdominal organs. The causes and results of such migration were studied in the light of literature on the subject, and the personal experience of the author. Case 1 was an irregularly shaped subperitoneal fibroid, the size of a fist, attached to the uterus by a very slender pedicle. The latter was very friable and broke away from the uterus during the removal of the latter. The omentum was attached to the posterior surface of the fibroid and partially nourished it. Case 2 was one of subperitoreal uterine fibroid, the size and shape of a normal kidney, connected with the uterus by a narrow pedicle, twisted once on itself. The tumor was situated on the right uterine horn, although the pedicle came from the other horn. The tumor was also attached to the bladder, pelvic peritoneum, omentum, and appendix. Case 3 was a hard, smooth tumor, the size of an orange, unattached to the uterus, having all the characteristics of a subperitoneal fibroid, surrounded on all sides by the omentum and nourished entirely by the omental blood vessels.

**Surgical Treatment of Ulcer of the Stomach.**—Dr. WILLIAM H. WATHEN of Louisville, after discussing the various pathological conditions indicating the necessity for stomach drainage, and the operations that had been performed, drew the following conclusions: "(1) Some cases of acute and subacute gastric and duodenal ulcer, and many cases of chronic and duodenal ulcer, should be treated by efficient stomach drainage into the duodenum or jejunum. (2) Drainage by pyloric divulsion and by pyloroplasty with its modifications has not been successful, and these methods are now practically obsolete. (3) Gastroduodenostomy, as modified by Kocher and Finney, may give efficient drainage in many cases, but it should be limited to such cases as cannot be operated upon by a posterior retrocolic gastroenterostomy with the anastomosis near the duodenojejunal flexure. (4) Anterior anticolic gastroenterostomy should not be an operation of election, but an operation of expediency or necessity, to give temporary relief, or to meet special abnormal conditions that may contraindicate the posterior attachment. (5) The ideal operation of election must be the posterior retrocolic attachment near the beginning of the jejunum, and at the bottom of the stomach in the pyloric end, thus eliminating the loop. (6) This gives the most efficient drainage, prevents the vicious circle and regurgitant vomiting, leaves

stomach and intestines in nearly normal relation, and is followed by better immediate and ultimate results. (7) The intestinal incision should be made longitudinally, and not less than two inches long, and the stomach incision of corresponding length, preferably in the oblique direction. An elliptical strip of mucosa should be incised from both stomach and intestinal incision. (8) The anastomosis is best made with a continuous suture (Pagenstecher or silk), using a full curved round-pointed needle. The suture should be applied in double layers, the inner to include all the visceral layers, and unite the cut edges of the opening; the outer one-fifth inch away, to include the serous and subserous layers. (9) Enteroenterostomy, or closure or resection of the proximal jejunum or the pylorus is unnecessary. It commits a traumatism and leaves a deformity that may cause immediate and subsequent bad results."

**Clinical Types of Pregnancy Toxemia.**—Dr. J. Clifton Edgar of New York contributed a paper with this title, in which he considered the benign type, subacute type, acute type, fulminant type, toxemic coma without convulsions, acid toxemia simulating hepatic pregnancy toxemia, persistent hyperemesis without clinical symptoms of toxemia, etc. Cases illustrating each type of toxemia were reported.

**Renal Insufficiency.**—Dr. Henry C. Coe of New York contributed a paper on this subject. This referred not only to diminished amount of urine, but to deficient excretion of urea, with or without accompanying albumin and casts. The importance of this subject could not be overestimated, on account of its direct bearing on the prevention of eclampsia. He mentioned the erroneous views formerly held that eclampsia always came suddenly, without warning. Now it was known that danger signals were seldom absent long before the attack, if careful watch was kept over the urine. Diminished urea, not the presence of albumin, was the important point. There were two channels for the excretion of toxins, the kidneys and the intestines. Both must be made use of. The kidneys and bowels should be flushed, and the diet regulated all through pregnancy. One should know the daily amount of urine at frequent intervals, and the amount of urea. One should not wait for general evidences of toxemia, gastric disturbances, pruritus, headache, etc., but anticipate them. Preventive medicine had nowhere more important application than in the case of a pregnant female. Everyone had had occasion to reproach himself for carelessness in this particular. Illustrative cases were cited.

**Pernicious Vomiting of Pregnancy.**—Dr. J. Whitridge Williams of Baltimore, after pointing out the distinction between vomiting of and vomiting in pregnancy, divided the former into three groups, and discussed their nature, etiology and treatment, namely, reflex, neurotic, and toxemic. The reflex vomiting of pregnancy might be due to the presence of abnormalities of the generative tract or ovum, which existed prior to the onset of pregnancy, or were coincident with it. Among such conditions might be mentioned retrodisplacements of the uterus, ovarian tumors, certain forms of endometritis, and abnormalities of the ovum, such as hydatidiform mole, hydramnios, and certain cases of twin pregnancy. The observations of the author and others showed that typical lesions might be found at autopsy in certain cases, and these consisted in the necrosis of the central portions of the liver lobules, and fatty degeneration and necrosis of the secretory cells of the kidney. Such changes could be produced only by the circulation in the blood of some toxic substance, which acted destructively upon the cells in question. The occasional occurrence of jaundice in some cases added confirmation to the existence on an hepatic lesion; while the not infrequent association of peripheral neuritis with the vomiting accentuated the probability of its toxemic origin. The liver lesions were identical with those observed in acute yellow atrophy of the liver, and icterus gravis, though in most of the cases of vomiting no marked diminution in the size of the liver had been noted. As the former affections occurred usually in the second half of pregnancy, and the vomiting in the first half, it seemed probable that the effect of the toxemia varied somewhat with the duration of the pregnancy. At present, we were unacquainted with the exact nature of the toxic substances, though they were supposed to be metabolic in origin, but whether derived from the mother or fetus, or both, was not known. All that was definitely settled at present was that we had to deal with a toxemia, which gave rise to serious lesions in the liver, and later in the kidneys. That the latter were secondary in character was indicated by the fact that the urine did not contain albumin or casts until shortly before death. Associated with these lesions was a striking change in metabolism, manifested by a marked increase in the percentage of the total nitrogen of the urine put out as ammonia, which, instead of being two to five per cent., as normal, might rise to 16, 32, or even 46 per cent. Whether the increased ammonia output was due to the fact that the liver lesions interfered with the normal oxidation of nitrogenous material, so that large amounts escaped conversion into urea, and were therefore excreted in a less highly oxidized form, as ammonia, or whether it represented an attempt to neutralize an acid intoxication, was as yet undetermined. The practical point established was that a marked increase in the percentage of the urinary nitrogen excreted as ammonia indicated the existence of a serious toxemia, which, if allowed to continue, would bring about lesions in the liver and other organs inconsistent with life, and accordingly abortion should be induced as the only hope of saving the patient. It was probable that an ammonia output of ten per cent. represented the danger signal, and as soon as it was reached immediate interference was demanded. In the reflex and neurotic forms of vomiting, the ammonia output remained normal, and accordingly in such cases the treatment should consist in correcting genital lesions, if present, and the employment of mental suggestion and rest cure. There were at least two forms of toxemia of pregnancy, one giving rise to pernicious vomiting, and acute yellow atrophy, and the other to eclampsia. These conclusions as to the nature of the vomiting of pregnancy were based upon a number of imperfectly observed cases in previous years, and seven carefully studied cases occurring during the past two years.

**Eclampsia and Its Treatment.**—Dr. Cyrus A. Kirkley of Toledo, Ohio, said that other toxins than urea might produce eclampsia. Mixed infection was most probable. Renal insufficiency rather than albuminuria was an etiological factor. Although the source of the toxins was unknown, recent research rather pointed to functional disease of the liver. Prophylactic treatment, as a rule, was successful, and this consisted of means to promote elimination through the great emunctories. Venesection in suitable cases, both as a prophylactic and curative measure, stood first in the list of remedies.

**The Treatment of Eclampsia.**—Dr. Franklin S. Newell of Boston, before considering the curative treatment of eclampsia, discussed the prophylactic treatment, because there was little question but that eclampsia was a preventable disease in the great majority of cases, even in those who developed the signs of toxemia. Prophylaxis should be directed to the prevention of any accumulation of waste products at any period of pregnancy, combined with the ordinary hygienic measures to maintain and improve the patient's general condition. The treatment, to be efficient, should have four distinct objects in view: (1) The prevention of further absorption of toxins by the removal of the cause; (2) limitation of damage by the toxins already in the system; (3) elimination of the toxins, and (4) treatment of the patient. These objects were discussed in consecutive order, and at considerable length. As to after-care of the patient, for some days after the acute process had subsided the patient should be kept on a liquid diet. Absolute quiet and freedom from care were

imperative, and free excretion should be maintained. Sedatives and stimulants should be used as indicated.

**Vaginal Cesarean Section, Its Indications, Advantages, and Technique.**—Dr. HENRY D. FRY of Washington, D. C., said that the chief indications for the employment of vaginal cesarean section, and that which had mainly led to its adoption, were the prompt and easy emptying of the uterus in cases of grave eclampsia. Other indications claimed were cancer of the uterus, rigidity of the os, threatened rupture of the uterus, prolapse of the funis, placenta previa, heart disease in the pregnant woman, and hemorrhage from the normally implanted placenta. The writer entertained grave doubts regarding the application of this operation or any other method of rapid dilatation to the treatment of plactent previa. The reduced maternal mortality from this serious complication was largely due to recognizing the value of slow dilatation. One might be tempted to employ it in a vix, but this condition presented the limited field assigned to abdominal cesarean section. He summed up the various indications for this new operation. The advantages of vaginal cesarean section were the rapidity with which the uterus could be emptied. From six to ten minutes was all the time that operators had reported necessary, and as they became more familiar with the technique, it might be further reduced. Few operators had done more than one or two operations. Twenty to thirty minutes should complete the sewing up of the wound. There was little traumatism, and a clean surgical cut to sew up instead of leaving a lacerated surface. In eclampsia the blood resulting from the operation was beneficial, and the patient was returned to bed in the best condition to overcome toxemia.

**The Mortality of Operations, Other Than Strumectomy, in Cases of Exophthalmic Goitre, with Special Reference to Gynecological Operations.**—Dr. BARTON C. HIRST of Philadelphia said that to learn the collective experience of American surgeons with Graves' disease complicating operations, 366 letters were despatched to the members of the National Societies of Surgery and Gynecology. Forty-three surgeons reported sixty-nine cases. This number added to the six collected and reported by Sanderson, made a total of seventy-five. Of this number, thirteen died. In eleven of these fatal cases, the cause of death was expressly stated to be acute thyroidism, with tachycardia to an extreme degree, and eventual heart failure. In one case of appendiceal abscess the patient died of the combined effects of sepsis and thyroidism. In another case of pelvic abscess, the patient died under chloroform before the operation was begun. Excluding these two cases, the mortality from thyroidism was 14.6 per cent., or, including them, 17.3 per cent. The character of the operation seemed to have made little difference in the results. The mortality of the minor operations was 16 per cent.; that of the hysterectomies and myomectomies, 13.3 per cent. It appeared, therefore, that the existence of exophthalmic goitre added about 15 per cent. to the mortality of any operation performed upon the patient. In the first of the author's patients, there had been a distinct goitre and exophthalmos for years, but the tachycardia was moderate. The symptoms in this case were never very alarming, and soon yielded to treatment. It was not known that the second patient had Graves' disease until two days after the operation, when the pulse rose to 180; the eyes protruded, and the throat swelled. He then learned that since girlhood the woman had been subject to such attacks, but lately had been free from them. Although some improvement was shown after hypodermoclysis, purgation and heart stimulants, on the first day that symptoms appeared, a rapid and complete recovery was secured in the next three or four days, apparently in consequence of the administration of suprarenal extract in three-grain doses every four hours.

**Sudden Death During or Immediately After the Termination of Pregnancy or Operation on the Pelvic Organs in Women.**—Dr. EDWARD P. DAVIS of Philadelphia reported three instructive and interesting cases, and presented a table of twenty-five typical cases, selected from 193 papers on the subject consulted, and drew the following conclusions: (1) That sudden death might occur after abortion, labor, or operation, from undemonstrable causes. (2) Death might follow abortion, labor, or operation from the rapid formation of a pulmonary embolus. Examination of cases showed that this happened after so many different procedures that it was impossible to designate any one operation or manipulation which produced it. Pulmonary embolism might develop before the placenta had been delivered, or when delivered by Crede's method; although it was impossible to select any one manipulation which produced this accident. It was not frequent after cesarean operation, nor after the more complicated obstetric operations. Predisposing and probably exciting causes were bronchial infection and abnormal conditions of the blood. In 18,800 women in childbirth, or having operation, thirty cases of immediate pulmonary embolism occurred, with a mortality of 73 1-3 per cent. Diagnosis, respiratory spasm, with continued heart action. Treatment, hypodermatic stimulation, and electric current. Intravenous saline transfusion had not been proven efficient. (3) Primary thrombosis and secondary embolism might cause death after the termination of pregnancy or operation. Causes: Preexisting infection, mechanical violence, altered conditions of blood serum, and lesions in the walls of the vessels. Most important symptom, Mehler's sign, rapid pulse. Temperature curve in these patients fell on the third or fourth day, while the pulse curve rose. Death usually occurred from secondary formation of the pulmonary embolus. Treatment consisted in absolute rest, bandaging of extremities, and in some cases abdominal section with ligation and excision of the veins of the broad ligament. Pulmonary complications developed in 25 per cent. of the cases. Thrombosis was most common in vessels connected with the left iliac vein. There was not conclusive evidence that the entrance of air into the veins was a sufficient cause for death. Gas might form in the vessels from infection. (4) Sudden death occurred in parturient women, and after operation, from reflex nervous shock, without assignable cause; also from disease of the thoracic viscera, from infection of the placental site, and other obscure conditions. Patients having fibroid tumors were especially liable to disease of the heart and vessels.

**What Is the Present Status of Electricity as a Therapeutic Agent in Gynecological Practice?**—Dr. CHAUNCEY D. PALMER of Cincinnati, Ohio, spoke of the importance of this agent, and referred to its evolution. He referred to the value of measuring the current in individual cases, and discussed at length in what classes of gynecological cases electricity was useful. The possibilities of electricity as a therapeutic agent were by no means limited. The object of the paper was an effort to speak of electricity and place it on its proper basis, not to magnify or misrepresent its virtues, nor to depreciate its powers.

**Officers.**—The following officers were elected: *President*, Dr. R. B. Maury, Memphis, Tennessee; *First Vice-President*, Dr. Howard A. Kelly, Baltimore, Maryland; *Second Vice-President*, Dr. Reuben Peterson, Ann Arbor, Michigan; *Secretary*, Dr. J. Riddle Goffe, New York City; *Treasurer*, Dr. J. Montgomery Baldy, Philadelphia, Pennsylvania.

Hot Springs, Virginia, was selected as the place for holding the next annual meeting.

---

**Ovarian Cyst; Sarcomatous Degeneration.**—Lorrain reports an interesting case. The patient exhibited the clinical symptoms characteristic of ovarian cyst with a twisted pedicle. When the abdomen was opened a dermoid cyst of the ovary with sarcomatous degeneration was discovered. A perforation of the cyst was noted. Its wall showed here and there epidermis, an enormous tuft of hair, and black vegetations, which histological examination proved to be sarcomatous tissue, stained with melanin.—*La Presse Médicale.*

### Philadelphia Pediatric Society.

At a stated meeting held June 13, Dr. Edwin E. Graham exhibited "A Case of Congenital Heart-disease in an Infant of Eight and a Half Months." The patient presented, in addition to cyanosis of the extremities and the lips, a systolic murmur, best heard at the apex of the heart. The condition was believed to consist in a perforate ventricular septum, possibly with a patulous ductus arteriosus. Drs. G. M. Astley and C. F. Judson exhibited "A Case of Recovery from Ulcerative Endocarditis." The patient was a boy about six years old, who presented symptoms of rheumatic polyarthritis to which subsequently were superadded heart-murmurs with a hectic type of temperature and sweating. A diplococcus developed on culture of the blood. Varied treatment was employed, including intravenous injections of a solution of colloidal silver, but without apparent effect. Recovery, however, eventually took place, and the child exhibited merely a soft systolic murmur at the apex of the heart. Drs. T. Turner and J. H. McKee exhibited "A Case of Interlobar Empyema." The patient was a child about seven years old, in whom following an attack of croupus pneumonia symptoms of some abnormal intrathoracic conditions persisted. Puncture disclosing the presence of pus excision of a rib, was practiced, and an accumulation in the cleft between the lobes of the left lung was evacuated. Drs. J. H. Jopson and J. E. Talley reported "A Case of Interlobar Empyema Following Pneumonia." In this case also, puncture disclosed the presence of pus not containing pulmonary tissue, and other evidences of lung-destruction, so that the presence of an empyema was diagnosticated. Accordingly, a portion of a rib was resected, the accumulation evacuated and drainage provided for. The result was entirely satisfactory and recovery was complete. Dr. Horace H. Jenks read "A Note on a Series of Cases of Stomatitis." These occurred in the Children's Hospital, and were characterized by multiple ulceration, usually in three situations, most commonly each cheek and the lower lip, in some instances with the presence of Klebs-Loeffler bacilli and in one or two requiring excision and cauterization with pure nitric acid. The condition presented certain resemblances to aphthous and ulcerative stomatitis, from which, however, it presents certain features of differentiation.

### Philadelphia County Medical Society.

At a stated meeting held June 14, Dr. Wm. L. Rodman demonstrated a young woman from whom a large goiter had been removed with perfect success. The enlargement extended deep behind the sternum and it was, therefore, not so obtrusive as it would otherwise have been. Dr. Rodman demonstrated also a man from whom a large calculus had been removed by means of suprapubic cystotomy. Rupture of the bladder occurred after the introduction of eight ounces of fluid, but fortunately the escape took place into the prevesical space, and no harm resulted, as incision was made without delay. Dr. Rodman reported a case of cancer of the cecum in which it was found impossible to remove the growth after the abdomen had been opened. Accordingly enteroanastomosis was established by the posterior route, and the subsequent improvement was extremely gratifying. Dr. Rodman reported additionally a case of perforated gastric ulcer in which classical symptoms had at no time been present. Operation, however, was promptly undertaken on the development of symptoms of perforation, the margins of the opening in the stomach being sutured, and recovery took place. Dr. Rodman demonstrated a case of ulcer of the stomach in which gastroenterostomy by the posterior route was performed. Ulcers were found at the pylorus, and the operation was followed by eminently satisfactory results. Dr. Rodman finally demonstrated a case of carcinoma of the stomach in which gastroenterostomy by the posterior method was performed to the great advantage of the patient.

Dr. T. Turner Thomas presented a communication entitled "Fractures of the Head of the Radius; Report of Two Cases: An Experimental Study; Preliminary Communication." He contended that fractures of the head of the radius are probably more common than is generally recognized. The injury is usually, if not always, inflicted by a fall upon the palm of the hand, held in such a manner as to receive the weight of the body, and thus driving the external condyle of the humerus upon the head of the radius. The fracture may be oblique or transverse. In addition to pain and swelling, the only other symptom may be impaired mobility, crepitus often being wanting in consequence of impaction of the fragments or from the action of the obturator ligament. The lesion may not be disclosed in skiagrams made even by expert operators. In the way of treatment the parts should be immobilized for two or three weeks, and then passive movement cautiously be begun.

Dr. Moses Behrend read a paper entitled "Perineal Prostatectomy Performed with the Aid of Young's Tractor; Report of a Case." The patient was a man, 75 years old, who had for many years complained of difficulty in micturition. The operation was performed without serious difficulty, and the result was altogether satisfactory.

Dr. W. Wayne Babcock read a paper entitled "Cervical Rib with Resulting Gangrene of the Fingers." The patient was a man who was compelled to incline his head to one side to relieve the pressure and pain superinduced by a cervical rib. The circulation in the upper extremity was greatly impaired in consequence of the relations of the subclavian artery to the supernumerary rib, the scalenus anticus muscle and the first dorsal rib. The fingers were pale, especially in cold weather, and the radial pulse was not palpable, and eventually gangrene occurred in the fingers. The abnormal formation was exposed by operation and removed, and the previous symptoms disappeared.

### St. Louis Medical Society.

At the stated meeting of this society Mr. Willard Bartlett read a paper on "The Value of Getting Certain Patients Up Very Early After Laparotomy," in which he laid stress on the fact that he referred to certain cases only in which there were definite indications for placing patients on their feet or in a chair within twenty-four or forty-eight hours after opening the belly. The majority of his patients remained in bed ten to fourteen days after the ordeal. He said the main danger in allowing them to be up very early seemed to be postoperative hernia; this was shown to be the result of a combination of four factors which were largely under control, viz., a wound improperly made, improper union of a wound, increased intraabdominal pressure and suppuration. The possibility of detaching an embolus from a thrombus formed in large pelvic or other veins, was to be dreaded late rather than early in convalescence. The author had allowed patients to assume the erect posture during the days immediately following abdominal section, for a number of reasons—because of great age or irremovable malignancy of the abdominal viscera, to facilitate abdominal drainage, to aid respiration and improve the circulation in the lungs, to help the appetite, to stop vomiting, to obviate the use of the catheter, and to assist the patients in evacuating the bowels. When such heroic treatment was undertaken, the abdominal wall was supported as well as possible by adhesive straps and a binder, though chief reliance was placed on the sutures, nonabsorbable material being used to support catgut temporarily in benign cases, and nonabsorbable sutures being buried in malignant cases. No hernias had followed the practice, though some of the patients had been operated on one and two years ago.

**A Whistle For the Wounded.**—A surgeon in the Japanese Red Cross service has invented a whistle which emits a very loud sound with a slight expenditure of breath. It is for the use of soldiers when they are wounded and desire to attract attention.

## Medical Items.

**Contagious Diseases—Weekly Statement.**—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 24, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 769 | 25 |
| Diphtheria and Croup | 207 | 24 |
| Scarlet Fever | 104 | 9 |
| Smallpox | ..... | ..... |
| Chickenpox | 115 | ..... |
| Tuberculosis | 462 | 148 |
| Typhoid Fever | 50 | 6 |
| Cerebrospinal Meningitis | 42 | 34 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1,749 | 246 |

**Boils and Carbuncles.**—R. F. Rand says that small boils often can be aborted in their incipiency by introducing with a needle or sharp probe a drop or two of pure carbolic acid. If a definite pus cavity has formed, simple incision, when good gaping of the wound edges follows, is quite sufficient for most small boils and a few larger ones. As a rule, if a small gauze drain is inserted there will be a free exit for the discharge and in a week, more or less, good granulations form and healing is uninterrupted. The tendency to reinoculation of adjacent hair follicles can be prevented and the comfort of the patient promoted by washing the skin with alcohol and applying hot antiseptic compresses of boracic acid or weak bichloride solutions. Large boils can be emptied more completely, and better drainage is secured, if a small oval piece of skin is excised. The best method of treatment for carbuncles is still unsettled. Excision has been advocated, but is certainly heroic if not impracticable in all but small carbuncles. It seems better to excise the central part of the mass of infiltrated tissue and to supplement this by multiple incisions in the larger carbuncles. Then the application of hot antiseptic compresses will soften the tissues and encourage the separation of sloughs.—*Yale Medical Journal.*

**The Art of Suturing.**—As Professor Mikulicz, the distinguished German surgeon, aptly remarks, "whoever has an opportunity of watching a surgeon operate can generally judge at first glance from his manner of suturing, the degree of perfection which his technique has attained." It is here that the dexterity of the surgeon most distinctly manifests itself. In spite of the numerous ingenious devices for facilitating the insertion of sutures, none of them surpasses the hand. The surgeon who has learned to apply stitches accurately and rapidly will often be able to shorten materially the period of operation, and thereby greatly diminish the risk of shock, and especially is this necessary in operative work upon the gastrointestinal tract. Mikulicz points out with justice that in the development of the purely scientific part of surgery there is danger of forgetting what might be termed the mechanics of the art. Nowadays there is scarcely any organ which may not require suture, and the successful treatment of wounds of the heart well exemplifies the importance of this subject.—*Indian Medical Record.*

**Acute Glaucoma.**—B. F. Church suggests to the practitioner upon diagnosing a case of acute glaucoma, the application of hot compresses over the eyes, renewed frequently for from fifteen to thirty minutes; the instillation of several drops of a solution containing eserine salicylate, one grain; cocaine, muriate, ten grains; and distilled water, one drachm. This is to be repeated every hour till the pupil contracts, with the exhibition of morphine to relieve pain and produce sleep. A full hot bath to induce free perspiration, the patient being immediately placed in bed, is an excellent preliminary to this treatment, but an immediate and active treatment of the underlying and predisposing general systemic condition is of the greatest importance to supplement and assist the local applications.—*California State Journal of Medicine.*

**To Remove Rust from Instruments.**—The instruments are placed over night in a saturated solution of stannous chloride, which causes the spots to disappear by reduction. The articles are then rinsed in water, laid in a hot solution of soda soap, and dried. It is well to rub them with absolute alcohol and prepared chalk. Another convenient method for removing rust is to lay the instruments in kerosene. Paraffin oil is the best preservative against rust, and the most convenient way of applying it without getting an unnecessarily thick coating is as follows: One part of the oil is dissolved in 200 parts of benzine, and the objects, after being thoroughly dried and warm, are plunged into the solution. Instruments with joints, as scissors or needle-holders, are worked in the fluid, so as to cause it to penetrate into all crevices, and the benzine is then allowed to evaporate in a dry room.—*Pharmaceutisches Zentralblatt.*

**Sterilization of Knives.**—H. A. Royster, as the result of experiments and of correspondence with a large number of operators, has reached the following conclusions: (1) Knives can be safely sterilized by chemical and mechanical means without the use of heat in any form. (2) The majority of American surgeons are using carbolic acid, or alcohol, or both. (3) Immersion in ninety-five per cent. alcohol has the least, and boiling the most effect in dulling the edge of a knife.—*Annals of Gynecology and Pediatry.*

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending June 24, 1905:

| | | Cases | Deaths |
|---|---|---|---|
| **SMALLPOX—UNITED STATES.** | | | |

### THE DETERMINATION OF INTESTINAL FUNCTIONS BY A TEST-REGIMEN.

By HEINRICH STERN, M.D.,

NEW YORK.

PROFESSOR ON SPECIAL MEDICAL PATHOLOGY AND THERAPY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BOSTON.

It is the general trend of internal medicine to detect functional disturbances and to determine their degree when physical changes are still wanting. To accomplish this end, the organ suspected of performing its functions inadequately is subjected to a test as to its efficacy, that is, the organ is caused to execute a definite amount of work and conforming to the manner in which it acquits itself of the task imposed upon it, the extent of its functional deficiency may be recognized.

The progress which has been made in gastrology is mostly due to the introduction of the functional testing methods. They consist in the main in the ingestion of known amounts of certain drugs or of food stuffs; the withdrawal, after a definite period, of the gastric contents; the chemical and microscopical examination of the latter, or of the urine or saliva, as to certain factors. These diagnostic methods are so simple and so readily executed that they enjoy great popularity among practitioners.

It is evident that if we have a well-defined—although empirically accepted—standard of comparison, which would enable us to recognize functional disturbance, and, for that matter, incipient organic disease of intestines and adjacent organs, enterology would soon make as rapid strides as its sister science. However, we encounter great difficulties in devising such a standard of comparison. Wishing to determine, for instance, the secretory activity of the stomach, we have to take into consideration the secretion of but the one organ. The secretory function of the intestines, on the other hand, cannot be learned per se, and, clinically, we will be always compelled to consider it together with that of the liver and pancreas. Again, the determination of gastric secretory activity demands the ingestion of but one simple test-meal or test-breakfast which is withdrawn by the stomach-tube from one to three hours afterwards, while the secretory function of the intestines and adnexa can only be ascertained in a rather approximate way, after ingestion of a series of test-meals, after a lapse of a number of days and without employing any artificial means for the removal of the intestinal contents. The changes which a test-breakfast lodging in the stomach for one hour can undergo during this period are well-defined and more or less limited under all conditions; additional, unforeseen alterations hardly ever ensue in the test-contents of any stomach. On the other hand, there is practically no limit of change of the ingesta of mixed character when they are lodged in the intestinal tract, and the interaction of secretions and disintegration-products is so manifold that it is almost impossible to conceive a rational standard of comparison.

It is, therefore, somewhat preposterous to speak of "normal feces." Were we able to obtain them we would have our logical standard of comparison. Furthermore, a standardized test-regimen is by no means productive of "standard" or "normal" feces. Two persons, for instance, may be affected with a similar functional intestinal disorder. To both is given the same test-regimen. The one assimilates the specific food better than the other. The natural consequence of this will be that the first excretes a smaller amount of feces than the latter, that these feces exhibit a different consistency, that they traverse the intestinal canal in widely different periods, and that they are at variance in composition, not alone quantitatively but qualitatively as well. Again, the reverse may be the case if a test-regimen of a different nature is ordered, *i. e.* when the individual who could not well assimilate the first series of test-meals is able, and the other in whom assimilation was good, is unable to anabolize the new test-food. Apart from the discrepancy in assimilative properties, both individuals may be subject to the self-same physiological disturbance, which, however, may escape detection or confirmation as the feces of both patients differ so widely.

Instead of "normal feces" we may, however, speak of "test-feces." This provides a less narrow and more rational standpoint for the clinician, because he is not hindered by certain limitations which the conception of "normal feces" undoubtedly presupposes. "*Test feces" I consider those intestinal contents irrespective of amount and consistency which are discharged between thirty and forty-eight hours after ingestion of known quantities of the food habitually consumed by an individual.*

Of course, the "test feces" derived from the food best suited for an individual, although reflecting the assimilative capacity of the latter, do not offer a readily adaptable standard of comparison as we need it in every day work. An absolute standard such as the one which we possess in comparing gastric function, we will presumably never obtain. At its best, a standard from which to determine intestinal function can serve for general orientation only; the study of the details in the individual instances demands tedious laboratory investigation.

After all, the practitioner wants very simple methods, even at the cost of accuracy. In devising a test-diet we must hence be more or less arbitrary and are compelled to disregard to a large degree the individual demands. Such a test-regimen should exhibit all classes of foodstuffs, in amounts properly to maintain the metabolic processes, and in that form calling forth least disturbance in the majority of persons submitting to the test.

The pioneer-work in simplifying coprological methods and in creating a basis for the examination of intestinal function has been done by Adolf Schmidt, of Dresden, partly alone, partly in conjunction with Julius Strasburger, of Bonn. It was and still is Schmidt's endeavor to elevate enterology to

the plane of gastrology and to simplify the testing-methods that they may be performed in routine examination. In my own work I have closely followed Schmidt's recommendations excepting such modifications which I found necessary to make. In the following I shall briefly allude to the test-regimen, the technique of examination of the "test feces" and the significance of the findings.

**The Test-Regimen.**—The test-diet, as stated before, gives results which can serve for general orientation only. It should fulfill the following requirements: (*a*)—It must be sufficient to keep the organism in metabolic equilibrium and the bowels in physiological distension. (*b*) It must neither be too bland nor irritating to any degree. (*c*) It must contain the three groups of foodstuffs in proper proportion and admixture. (*d*) It must be uniformly prepared and in plain style. (*e*) It must contain normal amounts of salts. (*f*) It must be ingested in proper amounts and only at those periods of the day when the patient is accustomed to take his meals. (*g*) It must be continued for two consecutive days.

Schmidt recommends a test-diet to be ingested for three or more days, the daily constituents of which are, 1,500 cc. of milk, 100 grams of zwieback, 2 eggs, 50 grams of butter, 125 grams of beef, 190 grams of potatoes and 80 grams of oatmeal. This diet exhibits daily about 102 grams of albumin, 111 grams of fat, and 191 grams of carbohydrates, hence 2,234 total calories. It is taken in five portions, at breakfast, second breakfast, dinner, afternoon, and supper. It is not stated how much, if any, additional water is allowed during the twenty-four hours. The amount of ingesta is the same for all persons submitting to the test.

The following objections may be raised against this test-regimen: (*a*) The unusually large amount of milk. There is little doubt that many healthy individuals and a majority of those affected with intestinal disease cannot digest large quantities of milk as recommended in Schmidt's test-diet. In some obstipation ensues, in others diarrhea. The resulting feces are abnormal in most instances. They are of little assistance in the recognition of intestinal disturbance, and, certainly, cannot be considered "normal feces," as which they are stamped by Schmidt. (*b*) Oatmeal is not well-borne by a great number of people suffering from gastric hypersecretion, amylolytic insufficiency, and intestinal hyperfermentation. Oatmeal being an unaccustomed food to these persons, and with difficulty digestible, it should not be incorporated in the test-regimen. (*c*) The caloric value of the nutriment may exceed the needs of certain individuals. It cannot be expected that the feces of a person who ingests twenty-five per cent. more than his organism demands, or is able to digest and assimilate, should reflect his normal intestinal function. The same amount of test-ingesta for all individuals submitting to the diagnostic procedure—irrespective of their weight and systemic needs—is rather illogical. The amount of test-ingesta should be adjusted to the demands and habits of each individual. (*d*) Five meals a day, the custom in Germany, would be an unusual institution in this country. It would call forth, to say the least, unusual intestinal conditions which in turn would be productive of rather abnormal feces. The intestines when tested for their functional activity must not be overburdened by large amounts of ingesta nor be unduly stimulated by the frequent introduction of nutritive material. The test-meal should conform to the habits of the individual, and should, therefore, be administered in three daily portions in the vast majority of instances. (*e*) The amount of water which may or should be taken with the test-regimen in addition to the liquids ordered must at least be known to the investigator. Water is not an inert liquid. It tends to regulate the osmotic conditions in the intestines and is of inestimable help in dissolving the ingesta and in the elaboration of the nutritive material.

Water, taken warm, is a cleansing agent, taken cold, it tends to increase intestinal peristalsis. Imbibed in large amounts, both warm and cold water is not without influence upon the condition and composition of the feces. Not partaken of at all, its absence will also be reflected in the intestinal discharges. The large amount of milk as advocated in the test-diet of Schmidt probably furnishes sufficient water in many cases.

To overcome the apparent deficiencies and to make its application more practicable, I have devised the following modification of Schmidt's test-diet:

The amount of total calories for each kilogram of bodyweight during the twenty-four hours, when at rest = 30. Of these calories 35 per cent. should be generated by carbohydrates, 45 per cent. by fats, and 20 per cent. by proteids. The amount of liquid (water) for each kilogram of bodyweight during the twenty-four hours = 35 c.c. An individual weighing seventy kilograms for the purpose of obtaining test-feces, should, therefore, receive per day an amount of food sufficient to yield 2,100 calories and about two liters and a half of liquid (water). Of these 2,100 calories, 35 per cent., that is 735, should be generated by carbohydrates, 45 per cent., that is 945, by fat, and 20 per cent., that is 420, by proteids. The test-regimen for a person weighing seventy kilograms would be constituted thus:

| *Breakfast.* | Albumin grams. | Fat. grams. | Carbo-hydr. grams. | Calories. approximately. |
|---|---|---|---|---|
| Cup of coffee..... | | | | |
| 20 c.c. of milk..... | 0.7 | 0.8 | 0.98 | 36 |
| 10 grams of sugar..... | | | 5. | |
| 3 eggs ..... | 19. | 18. | | 245 |
| 75 grams of wheaten toast.. | 5.25 | 0.38 | 36.75 | 183 |
| 15 grams of butter ..... | | 12.75 | | 119 |
| *Lunch.* | | | | |
| 200 grams of beefsteak medium fat; very rare—add to this, | 42. | 11. | | 266 |
| 20 grams of butter,..... | | | | |
| Mashed patatoes; | | 17. | | 158 |
| 100 grams of potatoes..... | 2. | 0.2 | 21. | 100 |
| 50 grams of milk..... | 1.75 | 2. | 2.45 | 35 |
| 1 yolk, ..... | 1. | | 5. | 50 |
| 30 grams of rice (boiled in water). When cooked add | 1.85 | 0.3 | 23.5 | 111 |
| 50 c.c. milk ..... | 1.75 | 2. | 2.45 | 35 |
| Cup of tea, ..... | | | | |
| 20 c.c. of milk ..... | 0.7 | 0.8 | 0.98 | 36 |
| 10 grams of sugar ..... | | | 5. | |
| *Supper.* | | | | |
| Cup of tea ..... | | | | |
| 20 c.c. of milk ..... | 0.7 | 0.8 | 0.98 | 36 |
| 10 grams of sugar ..... | | | 5. | |
| 3 eggs ..... | 19. | 18. | | 245 |
| 100 grams of wheaten toast, | 7. | 0.5 | 52.5 | 259 |
| 15 grams of butter..... | | 12.75 | | 119 |
| 30 grams of rice (boiled in water). When cooked add | 1.85 | 0.3 | 23.5 | 111 |
| 50 c.c. of milk..... | 1.75 | 2. | 2.45 | 35 |

This diet offers sufficient variety, and I have not as yet met any patient who has objected to take it for the short period of two days. In addition to the liquids specified in the dietary, the patient has to imbibe about one liter and a half of water daily. Schmidt recommends a test-regimen for three days, during which time he orders the feces to be accumulated and saved for the final examination. I find by practical experience that subsistence for two days on the diet as outlined before gives "test-feces," which serve our purpose as well as the so-called

"normal-feces." Besides, and this is an important point, the patient submits more readily to a two days' than to a three days' test-diet. Again, for obvious reasons, it is easier to accumulate the intestinal discharges from the thirtieth to the forty-eighth hour after beginning of the test-regimen than to save the entire evacuations for three consecutive days.

Some experimenters are in the habit of giving to the patient a coloring-substance at the beginning and the end of the test-diet. This will color the test-feces so that they may not be mistaken with other feces which might be excreted during the time of the investigation. These colors disturb the microscopical examination very much, and it is therefore better to try to do without them. By selecting a portion of the *uniform* feces which are discharged between the thirtieth and forty-eighth hours after starting the test-diet we are certain to obtain proper "test-feces" in the great majority of instances. Evacuation of the intestines by catharsis may be secured before the test-regimen is administered.

**The Examination of the "Test-Feces" in Routine Practice.**—The "test-feces" are all those intestinal excrements which are discharged after thirty hours from the beginning of the test-regimen. They must be obtained free from urine, as otherwise ammoniacal decomposition will ensue rapidly. It is best if urination and defecation occur into two separate vessels. Preserve jars with air-tight covers are well adapted as receptacles for the feces. The fresher the feces, the more trustworthy the results obtained by their examination. Preservatives must not be added to the test feces under any circumstances. If not analyzed at once, they should be kept in a cool place, well covered, until the investigator is ready to proceed with the examination. However, even if kept cool, it is not advisable to preserve the test-feces longer than twenty-four hours, as secondary decomposition processes, preventing recognition of the enteric function, will inevitably supervene. Again, if the clinician recognizes the fact that he may perform an examination of the "test-feces" sufficient for all practical purposes in about the same space of time in which he can accomplish a satisfactory uranalysis or an examination of the stomach contents, he will not put it off, but will try to proceed with their examination at once after he has received them.

A. Physicochemical examination.

Determine:—

*Color.* This is yellowish-brown in most cases.

*Odor.* Due to skatol from albumen decomposition. This is normal. If decidedly fetid, it is caused by an excess of fatty acids.

*Consistence.* Mostly formed. Unformed evacuations are not uncommon, and may be perfectly physiological. If hard, firm nodules, rapid absorption of water; if watery dicharges, insufficient absorption of water and non-tolerance of large amounts of starchy material.

*Reaction.* Mostly neutral, rarely directly alkaline. It is acid in the presence of pronounced fecal fermentation, especially when the evacuations are watery. The reaction is determined by placing a strip of red, as well as of blue, litmus paper *upon* a portion of the feces, previously reduced to a homogenous, thin paste by the addition of distilled water.

*Albumin.* Absent in the healthy condition of the intestines. Test for it by acidifying portion of test-feces with acetic acid, then make watery extract, filter repeatedly, and examine filtrate for various proteid substances.

*Pepton.* Absent in health. Examine for it by boiling watery fecal extract and filtering while hot. When cooled off, apply ferrocyanide of potash—acetic acid test for albumin. If positive, remove albumin by saturating with ammonium sulphate. Filter and examine filtrate for pepton by biuret reaction. If this pepton test is utilized, the aforementioned albumin test need not be applied, as it also reveals the presence of albumin.

*Hydrobilirubin.* Present normally. Examine by sublimate test. Some of the prepared homogenous fecal paste (quite watery) is placed in a small porcelain evaporating dish and mixed with some concentrated $HgCl_2$ solution, which has previously been put into the former. The mixture is left standing over night. In the presence of hydrobilirubin, the mixture attains a red color. The more recent and less decomposed the feces, the more pronounced the red color. In the presence of unconverted biliary pigment — bilirubin — we discover various-sized green-colored fecal particles.

*Fermentation test.* The test as described by Schmidt is as yet unsuited for every-day work. Besides, the results obtained by it are by no means of definite significance. Pathological fecal fermentation may be recognized without taking recourse to the fermentation test. Such abnormal fecal fermentation may be diagnosed when the intestinal evacuations appear frothy, when they possess the odor of butyric acid and exhibit an acid reaction. If the test could be executed without the assistance of an incubator and in less than twenty-four hours' time, it would probably be more frequently employed and prove of greater practical value.

B. Macroscopical examination.

The macroscopical examination of the "test-feces" is in many respects the most important. The clinician versed in fecal analysis will often recognize the intestinal insufficiency by their mere macroscopical study. The chemical examination of the "test-feces" will always remain of secondary importance, and their microscopical examination completes or confirms the macroscopical findings, but no more.

Sieving the feces by running a current of water through them when they are on a specially constructed sieve is a very good procedure when searching for biliary calculi, but for the macroscopical study of the feces, Schmidt's method, described in the following, is a much more rational one. The "test-feces" are well mixed, and a small portion (the size of a walnut) is placed in a glass mortar of about 350 c.c. capacity. Distilled water is slowly added to the feces contained in the mortar, which, by means of the glass pestle, are mashed as fine as possible (until of fluid consistence). The grinding must be carefully done until the fecal particles do not adhere together any longer. After this, the contents of the mortar are placed on a glass plate in the thinnest possible layer, and the macroscopical examination may be made.

If intestinal digestion is normal, the "test-feces" thus treated exhibit to the naked eye nothing but minute brownish articles:—cell-membranes of wheat and rice, elastic fiber, and connective tissue.

When abnormal conditions prevail, the following substances may be distinguished:

*Mucus* in any, even the smallest, amount. Pounding in the mortar does not always comminute the mucus shreds. Large plugs or cylinders of mucus are always readily recognizable, although the mucus of the colon when admixed with large amounts of fatty substances may lose some of its physical characteristics, attaining pronounced coloration and toughness. If in doubt as to the nature of the suspected floccule, resort must be taken to the microscope.

*Shreds of mucous membrane.* This points to membranous enteritis.

*Intestinal concretions and biliary calculi.* These are easily identified when the feces are comminuted or when they are spread upon the glass plate.

*Triple phosphates,* when occurring in great transparent masses. They occur sometimes in ammoniacal stools, and may be identified by the microscope.

*Débris of tendons and connective tissue.* These result from the ingested beefsteak, and are of pathological significance only when they appear as larger fibers and in considerable quantity. Schmidt opines that they are thus indicative of a gastric disorder. The threadlike appearance of the débris permits their discrimination from the mucous bands. If in doubt, add a drop of acetic acid to the fiber and place under microscope—if connective tissue, fibrous structure disappears; if mucus, it is brought into view.

*Débris of muscle tissue.* Small brownish rods. Recognized on account of their muscle structure when examined by the microscope. According to Schmidt, they point to an intestinal disturbance.

*Débris of potatoes.* Potatoes partaken of cold, as in the form of potato salad, always reappear in the feces in large, partly undigested amounts. In the form in which they are prescribed in the test-regimen they are not frequently macroscopically demonstrable in the feces. They may occur as small round or oval bodies, resembling mucus floccules or mucous clusters (frog-spawn), the latter not uncommon in mucous colic. The starch granules of the potato débris are colored blue by iodine, and have to be thus identified microscopically.

C. Microscopical examination.

The greatest value of the microscopical examination of the "test-feces" consists in the corroboration of the macroscopical findings. It is quickly executed if Schmidt's method is employed. A small particle of the finely subdivided feces of watery consistence is placed on each end and in the center of a glass slide. The first particle is at once spread in as thin a layer as possible with a cover glass, which remains *in situ;* the second fecal spot is treated with a droplet of acetic acid (30 per cent.), heated for a few seconds over the alcohol lamp, and covered with a cover glass; to the third fecal particle is added a small drop of Lugol's solution before the cover glass is applied.

The "test-feces," in the absence of functional disturbances, usually evince the following:

*First (native) Preparation.*—Heterogenous mass, consisting of granules, bacteria, etc., the exact nature of which is not discernible. Among the larger elements, we may distinguish connective tissue, elastic fibers, fragments of muscle fibre, cell membranes of wheat and rice, some unchanged starch granules, yellow calcium salts, uncolored soaps, mucus cells, epithelium from the alimentary tract, and cholesterin. All these elements occur in small amounts when the intestinal tract and its adnexa functionate properly. Appearing in large amounts, excepting probably the cholesterin, and in a less disintegrated form, they point to a more or less pronounced functional disturbance.

*Second Preparation* (treated with acetic acid).—This serves for the estimation of the entire fatty contents. Heating over the spirit lamp causes melting of all fatty substances. When cooled off, small flakes of fatty acids are seen throughout the entire field. Soapflakelets and the greater part of the lime salts have disappeared. Heated again, the preparation shows droplets instead of fatty acid masses if the slide is examined when still warm.

*Third Preparation.*—Rendered brown in appearance by the addition of Lugol's solution. A few unchanged starch granules appear blackish-blue; most starch granules are partly converted, and appear purplish. There are occasionally some isolated bluish discolored bodies, apparently not starch granules, to be distinguished.

In the presence of pathological conditions, we may find in the—

*First Preparation.*—Large amounts of muscle fibers, elastic fibers, connective tissue, fat droplets, fatty acid, and soap needles, large masses of cell membranes, and vegetable cells containing well-defined starch granules, puss corpuscles, a greatly increased number of epithelial cells, much cholesterin, greatly augmented quantities of oxalate, carbonate, and phosphate of lime, triple phosphates, and parasites and their ova.

*Second Preparation* (treated with acetic acid).—Very large amounts of fatty acid flakes, which greatly preponderate over all other elements in the microscopic field.

*Third Preparation* (treated with Lugol's solution).—Blue-colored starch granules, occurring free or within vegetable cells, yellow-colored yeast cells and various blue or purplish vegetable parasites.

56 East Seventy-Sixth Street.

## HISTORY AND WORK OF THE BEDFORD SANITARIUM FOR CONSUMPTIVES.*

By ALFRED MEYER, M.D.,
NEW YORK.

The causes apart from the purely humane ones that led to the founding of the Country Sanitarium for Consumptives of the Montefiore Home were threefold: First, the large number of consumptives that were being taken care of in the parent institution to the exclusion of other types of chronic invalids; second, the long waiting list of consumptives; third, the belief that better results would be obtained by caring for these cases in the country, with more abundant provision for sunlight and air and outdoor life than it was possible to obtain for them in the city. The initial fund was one of $50,000, contributed in equal shares by Mr. Jacob H. Schiff and Mr. Lyman G. Bloomingdale. After investigation of various sites during a period of two years, on June 5, 1897, a farm of 136 acres, with farmhouse and barn, were acquired at Bedford Station, Westchester County, by a committee of which Mr. Lyman G. Bloomingdale was chairman, and after suitable alterations were made, fifteen patients were accommodated during the eight weeks ending November 1, 1897. This was the modest beginning from which the present large institution, capable of accommodating 167 patients, has developed.

Bedford Station is situated on the Harlem River Division of the New York Central Railroad, about forty miles from New York, and twelve miles northeast of Ossining. It should not be confounded, as is very often the case, with Bedford Park, situated on the same railway, but within the limits of the Greater City of New York. The country is of charming, gently rolling character, the hills being the foothills of the Berkshires. The institution is on an elevation overlooking the village three-quarters of a mile distant, faces southeast, and is about 400 feet above sea level. Within the first year from the opening a pavilion designed to accommodate twenty-four patients was added, through the generosity of Mr. and Mrs. Leonard Lewisohn, who contributed $10,000 for that purpose. During the first year there was no resident physician. The whole

*Read at the First Annual Meeting of the National Association for the Study and Prevention of Tuberculosis, Washington, D. C., May 9, 1905.

number of patients, fifty-one for the entire year, "just shifted for themselves," as so many others of a higher social level do when they are sent away from home to get well from the climate alone. When a patient had an hemoptysis, a messenger had to be sent three miles over a country road, to Mt. Kisco, to get a physician. Proper supervision under such circumstances was an utter impossibility, and the directors, appreciating this fact, in September, 1898, installed a salaried resident physician-superintendent.

My own connection with the work in a consulting capacity dates from early in the year 1899. At that time the sputum was being sent for examination to the city, for there was neither microscope nor laboratory. Both defects were promptly remedied, and improved methods of keeping histories and of recording and charting clinical data were introduced. In July of that year the institution became one of the Official United States Weather Bureau Stations, and records of maximum and minimum temperatures, and of rain and snow precipitation, have been continuously kept since that time.

Pressure for admission was so great, and the enthusiasm of the directors so much stimulated by the results of their experiment, that it was determined to build an institution capable of accommodating 160 patients. Originally a number of laymen favored the cottage plan, after the pattern of the Adirondack Cottage Sanitarium of Dr. Trudeau. I am glad that I was able to prevail upon the gentlemen to give up this idea. The pavilion plan was ultimately adopted, more or less in the style of the Massachusetts State Hospital for Tuberculosis, at Rutland, giving the institution a great wealth of sunlight and air, with ease of ventilation, with much less cost than the cottage plan would have entailed, besides provision for a much larger number of patients at greatly reduced rates of administration, much readier and more accurate supervision of the patients, and finally adding to their happiness by permitting their closer association and union into a family—a union in keeping with their previous habits and instincts. The new buildings were dedicated in May, 1901, and it was very appropriate that Vice-President Roosevelt should have taken part in the exercises, not only because the antituberculosis campaign was at that time assuming national proportions, but for the more personal reason that he had, as Governor of the State of New York, kept his promise of signing a bill for a State hospital for incipient tuberculosis, and had done even more than he promised when he worked for the measure to save it from death in a legislative committee. He was thus instrumental in putting New York second in the column of those States providing sanatoria for the consumptive poor. The character of the institution being non-sectarian—recognizing neither a religious nor a scientific distinction between a Jewish tuberculosis and a Christian tuberculosis—it was also appropriate that Bishop Potter should have been present to speak a word of thanks and of encouragement. Oscar S. Strauss, ex-Minister to Turkey, voiced the appreciation of the charitable public on the successful completion of so large an undertaking, and bespoke for it the further sympathy and support of the well-to-do.

The new buildings were erected under the supervision of Buchman and Fox, architects, and present an unusually bright and cheerful appearance. They are all two stories in height, and consist of a central administration building, flanked on each side by two wings for male and female patients respectively, and are united on the northern aspect by a continuous glass covered corridor; their southern ends terminate in covered solaria and uncovered piazzas for the outdoor rest cure. In the basement are hydropathic department, drug store, morgue, power plant, carpenter shop, and store rooms for clothing and for crockery. In the rear, running at right angles to the corridor, are the power house, kitchen, laundry, and employees' dining room. We have our own plant for steam, electric light, and ice making.

The lower floor of one wing on each division, male and female, is broken up into separate rooms, arranged on each side of a central corridor. These accommodate one or two patients each and permit the isolation of advanced, complicated, and fever cases, and of those who are dying of their disease. This arrangement not only takes the place of the usual infirmary of some other sanatoria, but if need be permits the gradual hardening of the sensitive newcomer before admission to the wards, where, during the winter, the temperature often drops to 40 degrees. All the other floors are practically long wards. They are flooded with sunlight and air, and I am very fond of saying to the house staff when I get out, on a dark winter's day, that I envy the patients, for they are getting more air and sunlight for nothing at Bedford than I can get for a high price on Madison Avenue, New York City.

Water for the institution is obtained from an artesian well sunk over 400 feet, and easily furnishing 30,000 gallons per day. The sewage is disposed of in a series of sand filter beds after sedimentation in a series of septic tanks, according to the plan and method of the Bacterial Sewage Purification Company of this city. After the opening of the new building, the original ones were converted into a Synagogue and additional sleeping quarters for the help. The accessory buildings consist of a barn and dairy, a hennery, chief farmer's house, three tents on platforms, and the Blumenthal Pavilion or summer house for women.

The house staff consists of four medical officers, three graded and salaried, one unsalaried, but in the line of promotion in case of a vacancy. Dr. L. Rosenberg has been house physician and superintendent the past two years. Weekly visits are paid by me as consulting physician during the entire year, except when on my vacation, when the work devolves upon my adjunct, Dr. G. Mannheimer. The laryngological work is supervised by Drs. Toeplitz, Freudenthal, and Danziger in rotation. In case of need, the services of any member of the medical board of the Montefiore Home or of his adjunct may be claimed; cases for operation, unless it be a minor one, are transferred to the city institution. There are usually about ten orderlies and nurses employed,—the total staff of employes, medical and non-medical, aggregating about forty-eight. Every patient on his admission receives for his instruction and guidance a list of rules for consumptives printed in convenient form on heavy cardboard in English, German, or Jargon. The patient has his choice of language, which simply, though not elegantly, nor yet with perfect grammar, tries to make clear to him the nature and hopefulness of his illness and the influences that work for and against his recovery. He also receives a bottle with metal screw cap for his expectoration. Expectorating on floor or grounds is punished by instant dismissal. The sputum is emptied by patients into a large metal pail, where it is mixed with sawdust by orderlies, emptied twice daily into a special furnace, and burned. I regard this as the ideal method of sputum disposal. The pails are afterwards scalded in hot water and returned to their places on each floor. The sawdust which we get from a mill in a neigh-

boring village, costs us about $12 per annum. Three generous meals a day are served for all up-patients in the common dining room. Half-way between these meals and on retiring, milk and bread are served to any one wishing them. Shower baths are given daily to large numbers of patients, of such temperature and duration as insures thorough reaction, the latter being controlled by a nurse or a member of the house staff in charge. In some cases a preliminary course of spongings is necessary. Patients who do not take the showers must take a cleansing tub bath once a week. The temperature of patients is taken at least twice daily in the rectum. When this reaches 100 degrees plus, the patient must remain in bed until the normal has been maintained for several successive days. Continuous fever is treated by inunction with soluble silver, various coal-tar antipyretics, spongings, and the partial pack (Stammumschlag). Certain antisera were used hypodermically in a few cases once or twice daily for some weeks, but had no appreciable or unequivocal effect on the fever, and were open to the objection of causing severe urticaria. In a few cases the fever yielded immediately to quinine, when they were found to be cases of pulmonary tuberculosis complicated by plasmodial infection, an interesting combination of which I have seen four cases, two at Bedford, one in New York City, and one in the Adirondacks. A combination of eucalyptus, sulphur, and carbon, used by inhalation, as recommended by Dannelius in the *Berliner klinische Wochenschrift*, did not give results in the few cases in which it was tried that justified its extended use. Certain concentrated foods also had a limited trial. Sanatoria are naturally the proving ground of therapeutic research in pulmonary tuberculosis, for it is only where a large number of cases can be observed together that chance influences can be eliminated, either so far as improvement or retrogression is concerned, but this very fact makes these institutions peculiarly the object of faithful attention by pharmaceutical houses. It is, of course, possible to be ultra-conservative and yet a certain amount of conservatism in their management is absolutely necessary, as many of them would not only be swamped with new remedies, but their reputations would severely suffer. In the trial of any new remedy, whether in the nature of a drug, a serum, or a food product, it would appear preferable in most cases to select for trial such patients as have derived all the benefit attainable from the usual hygienic, dietetic, atmospheric, and hydropathic measures, and whose condition has become stationary under the sanatorium physician's eye. This is a severe test, I will admit, which at times may be departed from, but its conclusions at least are not misleading in attributing undue virtues to the thing tried. Treatment in the main, therefore, has been by aërotherapy, hyperalimentation, and hydrotherapy.

*Diagnostic Tuberculin Injections.*—In about forty-five cases in the past six years diagnostic tuberculin injections were used. In my judgment, such use of tuberculin is justified and is indicated in cases of suspected tuberculosis of the lung, in which the physical signs are negative, or, if present, of doubtful interpretation, in which there is no sputum, or in which repeated examination of the sputum does not show the presence of tubercle bacilli. Sanatoria for consumptives are a favorable field for the observation of these and other types. They often harbor patients in whom the bacteriological proof of tuberculosis is lacking or who may be suffering from emphysema, asthma, bronchitis, etc. The percentage of patients in whom bacilli have been found varies in different sanatoria, but in general it is not very high. In a series of 500 cases tabulated at Bedford a few years ago, 62 per cent. were positive bacteriologically. For comparison, I may say that the average in number of German institutions investigated by Pickert about the same time (*Ztschr. f. Tub. u. Heil*, 1902) showed only 45 7/10 per cent. of the patients positive, while at the Hanseatic Sanatorium Glueckauf, it was only 6 5/10 per cent. I expect at some future time to make a detailed report of my forty-five cases of diagnostic injections. It has been claimed, of course, that occasionally bacilli appear in the sputum after small diagnostic injections when they have been absent before. This is certainly infrequent in my experience; and when it does occur, not necessarily attributable to the injection. The same thing happens with every form of treatment, and with no treatment at all. We sometimes find bacilli and sometimes not, and in most cases their occurrence appears to be a part of the normal evolution of the disease. Some additional light might be thrown on this subject, if in a large number of negative cases sputum examinations were made daily for some weeks before, during, and after the diagnostic tuberculin injections, and the results compared with a large number of similar cases watched in the same way, during the same period, but without the injections. At Bedford, if the sputum on admission proves negative, it is re-examined every week or ten days. Even in positive cases the sputum is re-examined at stated intervals. Mustaches and beards are trimmed, as a rule, sometimes entirely removed. In a few cases we have struck a snag when a patient has regarded this appendage with a sort of religious fervor.

*Urine.*—The urine of every patient is examined on admission, the same as in a general hospital, including diazo reaction, and diabetics are excluded. A series of successive, positive diazos in our experience justifies an unfavorable prognosis, but in most cases seen at Bedford that conclusion could be reached by the other evidence alone; on the other hand, the absence of a diazo reaction does not justify a favorable prognosis. I believe that occasionally diazo reactions are not obtained because a half per cent. *nitrate* of soda solution is used in place of the *nitrite*, the druggist's nitrite having in part been changed while in stock by oxidation. The sticks of glassy looking nitrite then have a coating of snowy white nitrate on them—this latter should not be used in the preparation of the solution.

*Occupation.*—Non-febrile and convalescent cases are encouraged to assist in various light duties about the institution—bed making, waiting on table, driving the horses, getting the mail, and the like. During the spring, summer, and autumn about twenty-five patients put in a few hours a day in farm, garden, and orchard work.* The produce and supplies raised have been far beyond the needs of the institution, and the prize pumpkins, cabbages, radishes, and ears of corn would have done credit to a county fair. The value of such a régime to the patients themselves is simply inestimable. The outdoor life it encourages, the training in a useful and healthful occupation, the stimulus that comes with something accomplished, the reduction of the hours of loafing and brooding, all tend to the betterment of the patient, both physical and moral. A few years ago some of the boys were organized into a street cleaning brigade, given a distinctive sash to wear to develop an esprit de corps and, armed with long spiked sticks à la Central Park workman, they marched about the grounds with a wheelbarrow, under the

*Not during the past two years.

leadership of a foreman, stabbing and gathering such waste material as inevitably collects on the grounds. Similarly the women formed a sewing class and gathered at stated intervals in the solarium to ply the needle. The influence of this work on the temperature and general condition of the patient must be watched; even taking part in an entertainment may prove injurious. I have records of four cases in which the temperature was from one to three degrees higher on that evening than on the evenings immediately preceding and succeeding such effort.

*Duration of Stay.*—The complaint is frequently made that patients do not remain long enough in the sanatoria to arrest the disease. In some cases this is undoubtedly true. At Bedford the average stay for the first year was two months and twenty-five days, in the second year six months and twelve days, and the past or seventh year six months and ten days. But there is another side to the picture. Patients may also stay too long. It is a fair question whether it is reasonable to keep a patient more than one year, or eighteen months, if his condition has long been stationary, and there is, therefore, no outlook for further improvement. Cases of this kind not only occupy a bed to the exclusion of perhaps two patients a year, at six months each, who might have profited more than the chronic occupant, but the chronic occupant quite frequently becomes a source of mischief in the institution by his violation of its rules. Some of the worst offenders along this line were three cases that had been in the institution two years and two months, two years and six months, and five years and six months, respectively, and they were accordingly dismissed.

*Relapses and Vacant Lot Scheme.*—Partly because patients leave too early, partly because of the advanced stage of their disease, and their return to unsanitary surroundings and mode of life, Bedford, like other institutions, has had to face the question of relapses and readmission of former cases. An attempt has been made to control the situation in part by the passage of a rule denying any patient re-admission within a year who had left without the consent of the medical superintendent. An experiment will be tried this spring on a small scale of providing discharged men with a few hours' work daily, raising garden truck on vacant lots in The Bronx. A committee consisting of a few medical men, philanthropists, and real estate agents is just being formed for that purpose. One of the main obstacles, I fear, will be the disinclination to do this kind of work.

*Diagnosis.*—I wish to draw attention to a method of percussion employed by me, both at Bedford and at Mount Sinai Hospital, which often facilitates the recognition of slight dullness in the apices without, of course, giving a clue to the cause of the dullness. I have taught it to a considerable number of men who have worked under me. It is a method of continuous percussion at one point (supraclavicular, clavicular, or infraclavicular) while the patient is making one or two inspirations or expirations. The part, in place of being struck once, twice, or three times and then compared with the corresponding point on the other side is struck in rapid succession as much as twenty-five or thirty times while the patient is breathing in and out. The amplitude of the percussion stroke must necessarily be small and the force unvaryingly even, but both of these conditions can be fulfilled after some practice. The resultant series of sounds is wave-like in character in its rise and fall, and reminds me of nothing so much as the waves due to musical nodes produced by piano-tuners when tuning an instrument. The same method is repeated on the other side. A comparison of the two aural "pictures" produced in this way permits an easier recognition of slight changes, an easier comparison of the two sides, and an estimate of the aëration of the apices, or as often happens in old healed lesions non-aëration of this part of the lung. A somewhat similar method is employed in mapping the excursions of the diaphragm. You get an auditory "picture" that I would like to compare with the retinal picture produced by certain revolving toys of children, and perhaps the cinematograph and vitascope.

The growth of the institution from its small beginning is well illustrated by the figures of the last annual report. There were admitted during the year ending November the 1st, 1904, 244 new patients, the daily average number was 158, the highest number on any single day was 166, and the total number treated was 401. In 1902 in reply to an inquiry from a State officer as to where our army of cases comes from, our secretary, Mr. Ettinger, prepared a list, according to streets, of cases admitted during that year. Of course, the down town East Side gave the vast majority, 175 patients out of 247 during that year coming from below Fourteenth street and east of the Bowery, equivalent to 70 per cent. Thus Clinton Street had nine, Madison and Monroe, seven each; Delancey, Eldridge, and Essex, six each, and so on. Our patients pay us nothing, but every effort is made before admission to ascertain the applicant's claim to charity. A good idea of the great expense of running such an institution can be gained by the fact that $1,000 donated by a charitable lady for extra eggs that I might order, did not suffice to give one extra egg per day per patient for that year. It is not surprising, under these circumstances, that we were $38,000 short a year ago, and $22,000 short this year.

*Results.*—I have said but very little about the results obtained by this large outlay of money, thought, and labor. There is no generally accepted or perfect standard among medical men by which results at different institutions can be compared. We have tried to be conservative, and have classed as "apparently cured" those in whom fever, cough, and expectoration have ceased, who have improved in appearance, strength, and weight, and in whom râles could not be discovered, but who still had slight dullness or dullness and retraction at the site of disease; to this must be added the ability to do work for some weeks in the institution without evidence of evil effect. Cases were classified as "disease arrested," in which there were still cough and expectoration in reduced amount, and moist râles at the site of disease, but for months no fever or other evidence of extension or activity of the tubercular focus. These two types together made up about 17 per cent. of the 225 cases discharged last year. In addition over 54 per cent. were improved in various ways. If we estimate results by gains in weight alone (which, of course, is not entirely fair) our last year's record shows 78 2/10 per cent. out of 225 patients with gains to their credit. Our highest gain was 51 pounds.

I have neglected to say earlier in my paper that no dry dusting or sweeping is allowed in the institution—all cleaning is done with damp cloths.

And now, in conclusion, I would say that the profession generally can aid in the work of the institution, and of all similar ones in two ways: First, by the promptest possible recognition of the disease, often unrecognized by a too implicit faith in the negative sputum examination, or much less frequently an almost criminal neglect to examine the

sputum at all. Secondly, by the prompt recommendation of sanatorium care for those unable immediately to devote themselves to the problem of getting well in the way pointed out by science and philanthropy to be the only way. With these two conditions met, the tendency to make morgues out of sanatoria will, I believe, grow less and less. True, there will still remain in individual cases the problem of persuading an incipient case that he is sick enough to drop work, and in some cases all urging will be fruitless, especially if there is no cough—which, for the layman, is the *sine qua non* of pulmonary tuberculosis. But at least advantage should be taken of an initial hemoptysis, because it is a powerful lever to move the patient in the direction desired for his good, and (perhaps entirely on this account) because early hemoptysis cases are of better prognosis. I have often said to such patients that the hemoptysis is really a fortunate accident, a blessing in disguise. To hide the truth from the patient under these circumstances is to lose valuable time, and in all probability to excite his resentment when later he learns the truth. I have had pathetic complaints from people in regard to this deception and the injury done them by it.

## GASTRIC ULCER IN CHILDREN.*

By WILLIAM LELAND STOWELL, M.D.,
NEW YORK.

Ulcer of the stomach occurs at all ages; in infants, in the unborn fetus, and in octogenarians, but its infrequency during childhood makes the study of this and other cases of value to us.

On Tuesday, April 11, 1905, I was called to see a girl of 8 years who was evidently seriously ill. She lay with legs drawn up slightly, was breathing hard but not coughing, was extremely anemic, and had a cold skin bathed in clammy perspiration. The pulse was 100 and very weak, rectal temperature 98°. Her appearance was that of one dying from pneumonia. Physical examination revealed nothing wrong in the chest. We then paid more attention to the statement of the mother that all the child complained of was her stomach. The epigastrium was hard and tender to any pressure, and the abdomen was also distended, but not markedly so. The history was that the child had always been delicate, but never really ill except when she had measles four years ago; that the paleness had been noticeable since the holidays, and she complained much of headache, had dark rings under the eyes, etc.

On March 13 she left school because of headache and seborrhea of the scalp. She was treated at the Cornell Clinic by Dr. Wm. Shannon, who has kindly sent me additional history. Her appetite was good and bowels regular.

March 23.—Tongue heavily coated. Hands swollen one day this week.

April 10.—Monday, complains of pain in the stomach, with feeling of weakness. Anorexia. Vomited yesterday. Lips dry, tongue heavily coated. Pallor marked.

April 11.—I saw her in collapse as narrated above, and at 3 A. M. the next morning, after two hours of delirium, she died.

At 8 A. M. she was embalmed. At 1 o'clock, with the aid of Dr. Huey, I opened the abdomen sufficiently to permit removal of the stomach. The abdominal cavity contained a good deal of blood as well as embalming fluid, and when the stomach was withdrawn two perforated ulcers were found upon the posterior surface, about two inches from the pylorus on the lesser curvature. From one of these the blood must have come. Each perforation was about an eighth of an inch in diameter. There was no inflammatory action about them.

A review of the literature shows gastric ulcer to be fairly common, especially between the ages of 20 and 30, but rare in children. Rokitansky, for example, says he never saw a case under 14 years. Collin collected 279 cases of duodenal ulcer with a few gastric ulcers, 42 of which were under 10 years; 17 in the first year. Thirty-two thousand and fifty-two autopsies (made in Germany) showed 1,522 ulcers or cicatrices, *i. e.* 5 per cent. of those dying from all causes.

Fenwick, in 1897, collected 19 cases of ulcer in children and infants, to which I add others and my own. The following is a list of the published cases of gastric ulcer in children:

1. Author's case as described.

2. Dreschfeld: Girl, 14 years of age. Chlorosis. Severe dorsal pain and severe epigastric pain after eating, increased by walking. After a few months, hematemesis, melena, and death.

3. Northrup: Female, 1 year old. One month of diarrhea and vomiting, the latter brownish. Temperature 102° to 103°. Pulse 140 to 150. Death from exhaustion. Stomach contained many small ulcers and a large one that had perforated; necrotic not inflammatory.

4. Cheyne and Wilbe: Boy, 13 years of age. Thought to be fulminating appendicitis. Further operation showed a perforation of the anterior wall of the stomach, the size of a small slate pencil.

5. Keays: Girl, 16 years of age. Died before medical aid was secured. At the necropsy there was found a perforated ulcer on the anterior wall near the cardia and another on the posterior wall directly opposite. Was well until perforation occurred.

6. Malinoski: Girl, 10 years of age. Died of diphtheria and ulcer of stomach.

7. Wertheimer: Girl, 10 years old. Recovery.

8. Cade: Two months old. A single perforating round ulcer on the posterior wall near the pylorus. There was a large cavity behind the stomach with adhesions to the transverse colon.

9. Mackay: Female, aged 17 years. Perforation, operation four hours later, subdiaphragmatic abscess, but recovery.

10. Barker: Male, aged 10 years. Three or four days ill, collapsed and died in two hours. Autopsy showed four ulcerated areas in the stomach, two of which had perforated.

11. Billard, 1829: Aged 15 days. Ulcer penetrated to the peritoneum.

12. Billard: Aged 5 days. Died of hemorrhage from the stomach. The "ulcer was blackened as though it had been burnt."

13. Busch, 1836: Male, aged 7 days. Ulcer the size of a pfennig piece.

14. Buzzard: Female, aged 9 years. Discomfort after food for a short time. Perforation, death.

15. Rehn, 1874: Aged 21 months. Died of tuberculosis. Two ulcers in the stomach.

16. Binz, 1865: Female, 11 days old, with ulcer in center of lesser curvature.

17. Goodhardt, 1881: Infant, died of hemaemtesis 30 hours after birth. There was an ulcer one-eighth of an inch in diameter on the lesser curvature of the stomach.

18. Barlow, 1887: Female, aged 21 months, died of general tuberculosis. There were three ulcers nearly through the walls.

19. Colgan, 1892: Female, aged 2½ years. Gave no symptoms until 12 hours before death. Had a high fever and died in convulsions. An ulcer had perforated at the lower border of the fundus.

*Read before the Pediatric Section of the New York Academy of Medicine, May 11, 1905.

20. Fenwick, 1897: Female, aged 13 years, died of typhoid fever. Stomach and entire small intestine full of ulcers. Anterior wall of stomach adherent to the liver.

21. Fenwick, 1897: Female, aged 12 years, died from burns of arms and legs. There was an ulcer of the stomach the size of a sixpence.

22. Fenwick, 1897: Male, 10 years old. Right side pneumonia. Autopsy showed two ulcers of the stomach, one an inch in diameter, the other half an inch in diameter. The stomach was full of blood from an eroded blood vessel on the floor of one of the ulcers.

23. Fenwick, 1897: Female, 20 months old, died of noma and varicella. Two small ulcers were found near the pylorus.

24. Reimer, 1876: Female, 3½ years old. Indigestion two years. After measles had pain in the abdomen, constant vomiting, hematemesis, death from exhaustion. Ulcer near pylorus, whose base was pancreas. A branch of the pancreatic artery had been eroded, causing the hemorrhage.

25. Gunz, 1862: Male, aged 5 years, died of scarlet fever. He had an ulcer of the stomach, the base of which was adherent to the transverse colon.

26. Eröss, 1879: Female, aged 12 years, died of tuberculosis. She had nausea after meals, but never vomiting or hermatemesis. There were three gastric ulcers on the posterior wall, two of them small and one large. The latter, 2½ cm. in diameter, was completely perforated.

27. Rufz, 1843: Female, aged 13 years. Had "moderate dyspepsia" for several months. Died of perforation and peritonitis.

28. Chvostek, 1883: Male, aged 18 years at death. When 4 years of age he had epigastric pains after meals and continued to have such until death, 14 years later. He was greatly emaciated, looking like a boy of 10 years. Stomach enormously distended. One ulcer was 3 cm. in diameter, another near the pylorus, 2½ cm. in diameter, with thick edges and a base formed by the head of the pancreas to which the stomach adhered. The contracted pylorus would admit the tip of the little finger.

29. Leith, 1895: Female, aged 10 years, was eleven weeks ill with pneumonia, pericarditis, left pyo-pneumothorax, etc. A gastric ulcer had perforated the diaphragm and the stomach had become adherent to the spleen, from which there was a pus track to the lung. A bacterial culture produced pure staphylococcus pyogenes aureus.

30. Bechtold, 1904: Female, aged 5½ years, ill five months. Then had a sudden attack diagnosed as peritonitis due to appendicitis. An incision over the appendix liberated pus and other fluid, but the appendix was not diseased. At the autopsy, 48 hours later, the perforation was found in the greater curvature of the stomach.

31. Von Eiselberg, 1905: Female, aged 12 years, who suffered a year with pain and vomiting of blood. The pylorus had been adherent to the small intestine. There was great dilatation of the stomach. The pylorus did not admit the little finger. Gastroenterostomy was done, recovery was prompt, and the child was well three years later.

32. Fischer, 1900: Female, aged 9 years. For a long time had bloody vomiting and tarry stools. Chlorotic; lost 16 pounds in 6 months. Stomach greatly distended and tender. Chemical examination after test meal showed hyperchlorhydria. Later bulimia developed, followed by persistent vomiting. After prolonged medicinal and dietetic treatment she recovered.

33. Fischer, 1900: Female, aged 14 years, ill for long period. Vomited blood three years ago and suffered from anorexia, with distress after eating, and vomiting. The stomach contents showed an excess of HCL. There was chlorosis, emaciation, constipation, and headache. The blood showed marked polynuclear leucocytosis with diminished hemoglobin. She improved on fluid diet, bismuth, magnesia, and resorcin.

34. Bennett: Female, aged 16. For 18 months had pain after food, was relieved by vomiting. Sudden acute pain in epigastrium, followed by faintness. Operation two weeks later. Rigid abdomen, acute pain, distention. Respiration short and labored. Twelve ounces of pus drawn from chest without relief of abdominal symptoms. Ulcer perforated anterior wall of stomach. Patient left the hospital well.

35. Anderson: Girl, aged 16. Indigestion for three weeks. Intense abdominal pain above navel half an hour after hearty meal. Operation 21 hours after perforation. Died five weeks later of double pneumonia. Stomach was found soundly healed.

Why and how does an ulcer develop in the stomach? In the newly born the sudden change in the circulation may produce venous congestion which is followed by necrosis.

Hemorrhagic infiltration was the explanation of Rindfleish; embolism was the starting point according to Virchow. This etiology was generally accepted for many years. Arteriosclerosis will not answer as a cause in childhood, though it might explain some cases past middle life.

Sidney Martin gives bacterial necrosis a prominent place, and explains the frequency of ulcers near the pylorus by the absence of acid secreting glands there, the acid being a germ destroyer.

Poor food, bad air, mechanical pressure, etc., predispose in adults. Syphilis, typhoid fever, burns, and tuberculosis are also listed. Holt observed ulcer of the stomach in 5 cases among 119 autopsies upon children dead of tuberculosis. In none was the ulcer the cause of death. This frequency is nearly that obtaining in adults for all causes.

The site of the ulcer is usually in the lesser curvature and posteriorly. The analysis by Welch of 793 cases showed 36.8 per cent. lesser curvature, 29.6 greater curvature, 12 pylorus, 8.7 anterior wall, 6.3 cardia, 3.7 fundus, and 3.4 on the anterior curvature. Of those that perforate, the majority are on the anterior wall.

Some one has said that the symptoms may be absent singly or collectively, or may be latent. It must be true, as many ulcers are found unexpectedly at autopsy, and by contrast some die of gastric perforation with no premonitory symptoms or with illness of only a few hours. Infants give signs only of indigestion or gastric catarrh, with possibly hematemesis, or slightly streaked vomitus. A few have melena, dark pitchy stools caused by the hematin from the hemoglobin being reduced to iron sulphid. Rufz's case complained of "moderate dyspepsia" for several months. My case complained of nothing referable to the stomach until three days before death. Chvostek's boy suffered epigastric pains after meals for 14 years.

In Colgan's case, the patient, 22 years old, was apparently well until perforation occurred. Thus are extremes illustrated.

Anemia is extreme in prolonged cases, probably because of the disease; perhaps, as some claim, the anemia or chlorosis leads to ulcer. I believe in the former hypothesis.

A characteristic symptom in adults is a localized gnawing or boring pain in the epigastrium, which may also be felt in the back at about the ninth or tenth vertebra. The area is about the size of a silver

dollar, and is near the seat of ulceration. Pyrosis, heartburn, or water brash may appear. Food increases the pain, and vomiting relieves it by removing that which irritated the raw surface. Discomfort is increased by much sugar, much acid, highly seasoned, or very hot food. In the very young the symptoms are those of ordinary gastric catarrh. In a few instances an unusually hearty meal preceding perforation was doubtless its immediate cause. Vomiting is not always accompanied by blood, and rarely contains bile. The older writers always claimed that in gastric ulcer there is an excess of hydrochloric acid. Howard's records at the Johns Hopkins Hospital are more definite. Free hydrochloric acid was found in 82 per cent. of cases, but hyperchlorhydria in only 17.6 per cent. Free HCl is absent in 92 per cent. of cancer cases. However this diagnostic point is not needed in children.

Constipation is the rule. If hemorrhage occur into the stomach there is a peculiar feeling of distention and evidence of the same. If the hemorrhage be without, into the abdominal cavity, there is great pallor, a cold, clammy skin, a small, quick compressible pulse, a complete picture of collapse.

The medical treatment should be simple, but varied. Keep the patient in bed for bodily rest. Give nourishment so far as possible by the rectum, that the stomach may rest from digestive action and peristalsis. If food is given by mouth, it should be peptonized milk or milk with a cereal that will not admit of much firm curd. As the acids are greatly in excess, we give alkalies freely to neutralize them. Calcined magnesia is the best, to which may be added bismuth and cerum oxalate. Jacobi adds carbonate of lime to overcome the laxative effect of magnesia. An attempt may be made to heal the ulcer by giving silver nitrate in solution, or to those old enough to take it, in a pill with opium. Jellies and junket can be given the convalescent, and buttermilk, zoolak, or koumyss may be used throughout.

The prognosis does not depend upon age. Three-quarters of those ill recover upon proper treatment, some in a few months, others continue for long periods, as the boy in whom the ulcer existed fourteen years. According to Cruveilhier, "Simple ulcer of the stomach tends essentially to a cure;" "on the other hand, however, gastric ulcer may dispose to tuberculosis" (Dreschfeld). Hematemesis happens at all ages, but rarely causes death except as a factor in producing exhaustion. When there is erosion of a large artery enough blood may be lost to cause collapse. Infants die in this manner, but older children have perforation. Perforation in acute ulcers is usually sudden in symptomatology and resulting death. In chronic cases there may be inflammatory adhesions with neighboring organs as appears in the cases cited; two had pancreas as a base, one liver, one spleen, one diaphragm, and one colon.

Hour-glass contraction and other scar deformities are not mentioned in any child case thus far reported.

Operation on ulcer has been performed on hundreds of patients. For instance, Moynihan (1905) operated 153 times for chronic ulcer with but 2 deaths. His cases of perforation proved to be very different, viz., 22 operations with 63.6 per cent. of recoveries. The number of successful operations in childhood hardly admits of percentage rating. The only one in our list that recovered was 17 years old, so getting to young adult age.

In 1896 Weir and Foote gave the mortality for operation on perforations as 39.18 per cent., but technique is improving, so now Keen gives the mortality as 16.66 per cent. if the operation be done within 12 hours.

A summary of this subject will be made clear by the following Gastric Ulcer Percentage Table:

5 per cent. of all persons dying have gastric ulcer.
20 per cent. of all these have more than one ulcer.
40 per cent. occur in males, 60 per cent. in females.
75 per cent. are cured, judging by scars found.
18 per cent. last one year or less.
46.5 per cent. last from one to six years.
3 or 4 per cent. die from hemorrhage.
13 to 6.5 per cent. perforate fatally.
5 per cent. die from exhaustion.
50 per cent. have hematemesis.
40 per cent. of hemaglobin is lost from the blood.
20 per cent. of the red cells are lacking.
22 per cent. of cases are latent as to symptoms.
35 per cent. die without operation.
39 per cent. was the operative mortality for perforation prior to 1896. (Weir and Foote.)
16.6 per cent. is the mortality for perforation operations now if done within 12 hours. (Keen.)
1.3 per cent. is the operative mortality on chronic cases. (Moynihan.)

## SURGICAL ASPECTS OF GALLSTONE DISEASE.*

By JOSEPH WIENER, Jr., M.D.,
Adjunct Attending Surgeon, Mount Sinai Hospital.

Our knowledge of the pathology, and in consequence our ability to treat that complex phenomenon, gallstones, has of late years increased enormously. Only very recently have we begun truly to appreciate the rôle that inflammation—infection—plays in the production of gallstone diseases. For these diseases are most manifold. No longer are we content to make a diagnosis simply of gallstones. If we would accord our patient rational treatment, we must determine the location of the stone or stones in the biliary tract; we must determine the degree of inflammation present and its location; we must determine whether there is partial or complete obstruction to the flow of bile, before we can decide whether medical or surgical treatment is to be instituted.

* Read by invitation before the Eastern Medical Association.

Moreover, to the knowledge of pathology gained from thousands of operations on the biliary tract we owe the advance made in the rational treatment of gallstones. Nowhere in the whole range of surgery is it more true that "qui bene diagnoscit, bene curat." The prognosis varies greatly with the character of the inflammation and the location of the stones. There is hardly an easier abdominal operation than the removal of stones from the distended gall-bladder, hardly a more difficult one than the removal of those same stones from the common duct. The natural deduction would be to operate before the stones have entered the duct. Is this possible? In very many cases it is; provided, of course, we can obtain the consent of the patient. We know that the stones are in almost every instance formed in the gall-bladder; that they lie latent there for months or years, and that they do not leave the gall-bladder except after one or more attacks of inflammation, and often not even then.

The ideal method of treating this class of cases is to treat them medically during a few attacks. If one or more small stones are passed, followed by relief of the pain, then an operation is *not* indicated, because nature, by expelling all the stones present, may bring about a cure. If, on the other hand, one or more severe attacks of colic are not accompanied by the passage of any stones per anum, then an operation is indicated, and indicated long before there has ever been any jaundice.

But let us look at the pathological side of the question. In doing so we shall attempt to reply to two questions: (1) How can we recognize the different forms of cholelithiasis? (2) When is an operation indicated? The simplest method of classification is the following: (1) Stones in gall-bladder without obstruction of the cystic duct. (2) Stones in gall-bladder with transitory obstruction of cystic duct. (3) Inflammation of gall-bladder, cholecystitis, empyema. (4) Acute obstruction of common duct. (5) Chronic obstruction of common duct.

In all cases, except where there is obstruction of the common duct, jaundice is generally absent. And even where there is obstruction to the common duct, jaundice is not always present. In 80 per cent. of gallstone attacks there is no jaundice. The finding of stones in the stools is rare, because only in exceptional cases do the stones leave the gall-bladder during an attack. In chronic obstruction of the common duct the icterus is often very slight, and on superficial examination it may be overlooked. Indeed, there may be a large stone in the common duct, and yet there may be no icterus at all. This we see frequently at operations. On the other hand, there may be slight transitory icterus due to an inflammatory swelling of the mucous membrane of the duct, which prevents the bile from flowing past the stone. When the inflammation subsides, the bile can again flow into the duodenum, and the icterus disappears. With this condition there is often fever of the malarial type, and often chills at the time of the icterus. There may be fever without icterus or colics.

In cases of chronic obstruction of the common duct, it is important to ascertain if the obstruction is due to tumor or to stone. If due to stone, the gall-bladder is generally shrunken, not palpable, the icterus moderate and varying, the stool at times brown, at times gray, the colic of varying degrees of severity, the spleen generally enlarged, and the fever intermittent. If, on the other hand, the obstruction is due to cancer, the gall-bladder is enlarged, often palpable, the icterus is continuous and progressive, the stools are constantly gray, and there is generally an absence of colics, of enlargement of the spleen, and of fever. The puzzling cases are those in which there is a stone in the common duct at the site of the cancer.

That jaundice and gallstones go together is a popular but wrong belief, though an old one; in most cases of gallstone disease there is no jaundice. Jaundice is generally due to an inflammation of the gall-bladder, which spreads to the common duct. Only in the fewest cases is it due to an obstructing stone in the duct.

As above mentioned, most stones have their origin in the gall-bladder. Many stones, even several hundred, may remain in the gall-bladder a long time without causing any symptoms. Common as gallstones are, in 95 per cent. of the cases they cause very mild symptoms or none at all. Stones will produce no symptoms if the cystic duct is patent, if there is no inflammation in the gall-bladder, no adhesions, and if there are no changes in the wall of the gall-bladder. Stones may even be present in the ducts for a long time and cause no symptoms. There must be another element besides the presence of the stones to call forth symptoms. This other element, in the great majority of cases, is an inflammatory process in the gall-bladder itself. Only in the fewest cases is there obstruction of the cystic duct by a stone without a preceding or a concomitant inflammation. The colic is to be attributed to the stretching of the wall of the gall-bladder by the contained bile and inflammatory products, and not to the passage of a stone. The inflammatory process may force the stone into the cystic duct, where it may become impacted. Often, however, the stones do not leave the bladder. The mucous membrane of that viscus swells around the stone or stones, and the cystic duct may, by this inflammatory swelling, become completely occluded. The old theory that the colics only begin when the stones enter the cystic duct has been given up. In the great majority of cases the cause for the colic is the inflammation of the gall-bladder. This inflammation is either of hematogenous origin, or due to an infection from the gut, through the ducts to the gall-bladder. This explains how stones can remain for months or years without causing any symptoms, and how then severe symptoms suddenly develop. The result of an inflammation is a loosening of the mucous membrane of the gall-bladder and of the cystic duct, followed by a transudation of serous or bloody fluid into the gall-bladder. The bladder becomes distended, the nerve endings in its walls are stretched, and thus the well-known gallstone colic is produced. The more violent the inflammation, the quicker the bladder is distended and the greater the pain. A similar colic may be produced in a patient on whom cholecystostomy has been performed, if we inject salt solution into the gall-bladder.

The character and intensity of the inflammation depend on the number and the virulence of the infecting microorganisms. They may produce a serous, a seropurulent, a purulent, or a gangrenous cholecystitis. The inflammation may spread to the peritoneum, liver, and pancreas. Adhesions are formed, even a peritonitis may develop, without any perforation of the bladder. We observe similar phenomena in appendicitis, where no perforation has taken place.

If bile can pass it, a stone may remain in the common duct for months or years without causing any symptoms. The stone may slowly increase in size, without the patient having any knowledge of its presence. Suddenly, there is an attack of colic, jaundice or fever, or all three combined. One or two things has happened. Either an inflammation has taken place in the biliary passages, or there is an obstruction of the narrower portion of the duct near the duodenum. If the stone can pass the narrow

papilla, it will enter the gut, and, unless more stones are present, the symptoms will subside.

It is possible for a cholecystitis to be followed by a *restitutio ad integrum*. The bladder contracts on its contents and drives the bile and the exuded fluid through the ducts, washing the stone or stones into the gut. The ducts then being open, there is free drainage, and the inflammation may subside, leaving the patient practically cured of his cholecystitis and of his cholelithiasis. But in most cases this result is not attained. Even after repeated colics there are many stones remaining in the bladder, and the cystic duct may remain partly or completely occluded. A cystitis remains, or at least a hydrops of the gall-bladder, which is only too prone, at the slightest infection, to become the seat of a new inflammation.

If the cystic duct remains patent, the stones may, after the inflammation has subsided, remain quiet in the gall-bladder; and there may or there may not be a recurrence of the inflammation. As a rule, however, it does recur, and recurs only too frequently. The gall-bladder, like the appendix, when once it has been inflamed, is very prone to relapses. If we remember that the mucous membrane after a severe inflammation is never quite normal, that the constant presence of stones acts as a constant irritant, we need not be surprised that a cholecystitis so often recurs, but rather that it does not recur in every case. In place of the colic there may be a constant nagging pain referred to the back or to the stomach. Sometimes after an attack the general condition of the patient improves markedly, and yet the serous inflammation in the gall-bladder may be slowly becoming purulent, to burst out suddenly into the picture of a gangrenous cholecystitis, or even of a peritonitis. Here also we see a striking analogy to disease of that other abdominal organ, the appendix.

A local peritonitis with the formation of adhesions often develops around an acutely inflamed gall-bladder. The adhesions to the stomach, omentum, and gut, may produce serious symptoms, long after the acute inflammation has subsided. There may be stenosis of the pylorus, or kinking of the duodenum, with resulting dilatation of the stomach, and its long train of symptoms. Adhesions to omentum and colon may produce partial or complete intestinal obstruction. Moreover, the adhesions *per se* may cause such severe pain that an operation is imperative. At such an operation, frequently no stones are found at all, simply a chronic inflammation of the gall-bladder with adhesions. The adhesions may cause a kinking of the cystic duct, which produces overdistention of the bladder, and this in turn calls forth severe colic, which is often attributed to the presence of stones. The proper treatment in these cases is the removal of the gall-bladder; then there can be no recurrence.

Empyema of the gall-bladder may result in perforation through the abdominal wall, into the gut or into the peritoneal cavity. In any of these events spontaneous cure may result, just as it may in cases of appendicitis. However, the spontaneous cure in both diseases is the exception, and to wait for it is often to invite disaster. Stones may remain in the bladder or ducts in spite of perforation, and a new inflammation may be set up at any time.

Rarely do we find jaundice associated with inflammations of the gall-bladder. As jaundice only results when there is an obstruction to the flow of bile from the common duct, and as this obstruction takes place in only a small number of cases, we see that in the majority of our cases of cholecystitis and of cholelithiasis we have no right to expect jaundice to be present.

Kehr gives the following positive indications for operation:

1. Acute seropurulent cystitis and pericystitis.
2. Adhesions resulting from a pericystitis, if symptoms are present (pain, pyloric or duodenal stenosis, ileus, etc.).
3. Chronic obstruction of common duct.
4. Chronic obstruction of cystic duct.
5. All cases that begin mildly but are progressive, do not improve under treatment, and which incapacitate the patient from enjoying life or attending to his affairs.
6. Purulent cholangitis and liver abscess.
7. Perforation of gall-bladder and peritonitis.
8. Gallstone morphinism.

By an early operation we save our patient much pain and the dangers of suppuration, cancer, and peritonitis. And how much easier and less dangerous is an operation on the gall-bladder than one on the common duct? A cholecystectomy done early is not much more dangerous than an appendicitis operation in the interval. The danger of cancer developing in the presence of gallstones is real. According to Loebker, cancer of the biliary tract was present in 10 per cent. of his gallstone cases. In 162 operations for gallstones, Czerny found cancer 30 times, almost 20 per cent.

Stone in the common duct is so dangerous, not only on account of the difficulty of removing it, but also because the inflammation spreads from the duct to the smaller biliary capillaries. We then frequently are confronted by the picture of a cholangitis, with its terrible sequelæ. Obstruction of the common duct by a stone regularly leads to enlargement of the liver, which is regularly absent in case the stone is in the gall-bladder or cystic duct.

In rare instances, where there have been colics present before operation, no stones are found. The gall-bladder is found distended with turbid bile, and its mucous membrane is inflamed. These are cases of cholecystitis not due to cholelithiasis, but to an infection pure and simple, probably from the gut.

v. Winiwarter holds that the diagnosis of gallstones is an indication for operation, while Kraus, of Carlsbad, waits for a vital indication before advising operation. Does not the truth lie midway between these two extremes? Surely an operation for gallstones should not be an ultimum refugium. Some cases, *e. g.* seropurulent cholecystitis and empyema of the gall-bladder, are to be operated on as soon as the diagnosis is made. Other cases, *e. g.* those of repeated jaundice with passage of stones, can be treated for some time without operation. To give our patients the benefit of rational treatment, we must do more than diagnose the presence of gallstones. We must diagnose the location of the stones and the degree of inflammation present, and then we are in a position to decide whether or not an operation is indicated. Moreover, we must individualize, we must treat the patient and not the disease, always keeping in mind, however, that early operation in these cases is almost as free from danger as it is in appendicitis. If we would operate in every case in which we could make the diagnosis of gallstones, we would often operate unnecessarily. On the other hand, if we waited for a vital indication, *i.e.*, until the patient's life is endangered by the disease, before operating, then very often the patient would die after the operation; not as a result of the operation, but as a result of the delay in operating. Here, again, the analogy to appendicitis is striking. If in cases of appendicitis we do not delay operation too long, the overwhelming majority of our cases recover. The same is true of cholelithiasis. Unfortunately, however, the laity is not yet fully aware of the fact that

in these cases also early operation gives such brilliant results.

In many cases delay in operating is far more dangerous than operating. I need only allude again to the difference between removing stones from the gall-bladder and from the common duct. And yet we know that in the early stages of the disease the stones are almost always in the gall-bladder, and rarely in the ducts. The mortality after operations in the former class of cases is about 2 per cent., in the latter class about 20 per cent. Moreover, if septic or pyemic conditions supervene, or if cancer develops, the case is almost certainly hopeless. If we wait until complications require operations on the stomach, intestine, pancreas, or peritoneum, the operative mortality rises to almost 50 per cent.

Riedel's statistics prove conclusively that the danger of infection of the biliary passages is increased enormously as soon as one or more stones are lodged in the common duct. According to the same authority, and there are few more capable of judging, an operation should be performed after the first attack of colic without jaundice, provided no stones were passed. If, with the attack, there is jaundice and one or more stones are passed, then no operation is indicated.

The writer firmly believes that it is as wrong to wait for jaundice before advising operation for gallstones as it is to wait for peritonitis before advising operation for appendicitis. The worst time to operate for gallstones is when jaundice has developed; the worst time to operate for appendicitis is when peritonitis has developed. If we are sure the icterus is inflammatory, an operation is indicated. If the icterus is due to stone, it is dangerous to operate. But how often are we unable to say whether we have to deal with the one or with the other pathological condition? If the jaundice is due to the presence of a stone in the common duct, we wait. Not only is it a difficult and tedious procedure to remove such a stone, but there is also the added danger of shock, besides the great danger of hemorrhage due to the impairment of the coagulability of the blood. It is therefore much better to operate before any stones get into the common duct, before jaundice develops, before adhesions to surrounding organs have formed, before a cholangitis or a cancer has developed.

Choice of Operation.—The whole trend of modern progressive surgery is towards the removal not only of the gallstones, but also of the diseased organ in which they develop, the gall-bladder. Primary cholecystectomy is to-day the operation of choice in the large majority of cases of gallstones. The reasons for this are manifold: (1) The mortality is very small, lower even than after cholecystostomy. (2) The wound heals much more rapidly. (3) There is no danger of recurrence, either of the cholecystitis, or of the formation of new stones. (4) No secondary operations are necessary.

Naturally, stones in the common or hepatic ducts should be removed at the same time with the gall-bladder, and if necessary, drainage instituted either through the stump of the cystic or through the common or hepatic duct.

Even in empyema of the gall-bladder, where that viscus is enormously distended with pus, a primary cholecystectomy can be rapidly performed. The writer has in several cases removed such a gall-bladder in less than half an hour, and in one case in less than fifteen minutes. And further, the mortality after the complete removal of such gall-bladders is much lower than after simple incision and drainage. Naturally, if we operate before a severe infection has taken place, and before stones have traveled down into the common duct, our results will be still more satisfactory.

Only five years ago our operative mortality in cases of acute appendicitis was almost 20 per cent. To-day it is considerably less than 10 per cent. And why? Because the profession, as well as the patients, have come to realize the enormous advantage of early operation.

May we not hope that the time is not far distant when doctor and patient will be convinced that it is quite as important to operate for gallstones while the disease is still limited to the gall-bladder as it is to operate for appendicitis before the disease has spread beyond the appendix? When we have arrived at that happy stage, then, and not till then, will the results of gallstone operations be as brilliant as are those for appendicitis to-day.

## OBSERVATIONS ON A NEW METHOD OF ELICITING THE EXTENSOR PLANTAR REFLEX, AND ITS SPINAL LOCALIZATION.

By WILLIAM CHARLES WHITE, M.D.,
INDIANAPOLIS, IND.
PROFESSOR OF PATHOLOGY AND NEUROANATOMY, C.C.P. & S.

The present paper is written mainly to submit to other neurologists for experimentation a new method of eliciting the extensor response of the great toe, namely, by stroking the upper and inner surface of the thigh.

The reverse plantar reflex first described by Babinski in 1896 is now generally acknowledged by clinicians as one of the most valuable aids in determining the presence of involvement of the pyramidal tracts. More recent interest has been given to the reflex by Oppenheim and Gordon's describing their methods of eliciting the same phenomenon.

H. Oppenheim (Medical Record, Vol. 65, No. 1, p. 8) called attention to a reflex which occupies a position close to that of Babinski. Normally by stroking the inner surface of the leg from above downward with either the thumb or the handle of the percussion hammer, or, by pinching the inner surface of the leg there is produced either no reflex or a flexion of the toes. Under pathological conditions, *i. e.* in affections of the pyramidal tracts instead of a plantar flexion of the toes a dorsal flexion of the toes and foot is observed. This reflex differs from Babinski's not alone in the point from which the reflex is brought about, but in that not only the extensor longus hallucis, but also as constantly the tibialis anticus, the extensor communis digitorum, and the peronei participate in the movement. In the Babinski phenomenon, by stroking the sole of the foot only the extensors of the toes are made to participate. Oppenheim claims there are not a few cases in which the estimation of the toe reflex, according to Babinski, is uncertain and in such cases his reflex may prove decisive.

A. Gordon (*American Medicine*, Vol. III, No. 23, p. 971) under the heading, "A New Paradoxic Flexor Reflex, Its Diagnostic Value," describes another method of obtaining the same extensor response of the great toe. By grasping firmly and deeply the calf muscles, so deeply as to carry the pressure to the flexor muscles of the deep layer, he found that the great toe or all of the toes could be brought into the position of extension in many cases where the pyramidal tracts were involved. In other cases than those in which the pyramidal tract was involved the reflex was invariably absent.

I have found recently in a number of cases of in-

volvement of the pyramidal tract on one side that the same extension of the great toe can be elicited by stroking the inner side of the front of the thigh with the handle of the percussion hammer. The response to the irritation was at times confined to the extension of the great toe, at times to extension of all the toes, and, occasionally, when the Oppenheim and Gordon reflexes were absent, but the Babinski present, the stroking of the thigh gave definite and extreme extension of the great toe. Normally, on stroking the inside of the thigh either there is no response in the toes or they undergo (plantar) flexion.

In one case of hemiplegia in which the lesion occurred in infancy, the patient had grown to womanhood and was admited to the obstetrical ward, carrying an eight months child. She walked with a hemiplegic gait, but had gained considerable control

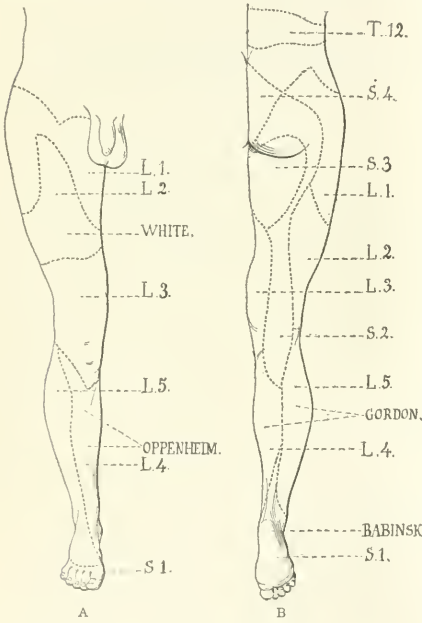

Diagram of skin areas of the leg and thigh corresponding to the different spinal segments; A, anterior, B, posterior aspect.
(From Osler's Practice of Medicine. D. Appleton & Co.)

over her leg muscles. Her arm was of little use and was the seat of contractures. At first the extensor reflex of the great toe could be elicited beautifully in all four ways, but toward the end of her confinement her legs became so swollen from edema that the Oppenheim and Gordon responses disappeared, but the irritation of the sole of the foot and front of the thigh still gave very definite extensor movement of the great toe. In all of these reflexes the readiness of response is greatly increased by coaxing, *e. g.* the Oppenheim reflex can often be obtained after several times producing extension of the toe by plantar irritation.

I have not had the opportunity to try this reflex on a sufficient number of pathological cases to prove its value, but wish to offer it for trial in other clinics. If the different diagrams of the segmental distribution of the sensory nerves to the skin of the parts primarily irritated to produce this curious phenomenon be examined, it will be seen that they involve at least four segments of the cord, viz., from the second lumbar in the thigh to the first sacral on the sole of the foot. The one thing common to all the reflexes is the extension of the great toe, which appears to be also the specific feature. This extension is governed by the contraction of the extensor longus hallucis. This muscle is represented according to Starr in the anterior horn of the fifth lumbar segment. Now one thing is certain that no matter where the irritation is applied it must in some way reach the anterior horn cells in the fifth lumbar segment that governs this muscle. I have reproduced here the diagram from Osler's "Practice of Medicine," modified from Head's diagrams as an indication of the skin distribution of the several segments. Most of the other diagrams conform more or less to this one. In this it will be seen that the sole of the foot is represented in the first sacral segment; the skin over the inner surface of the tibia (Oppenheim) in the fourth lumbar segment; that on the back of the leg (Gordon) in the fourth and fifth lumbar segments; that on the inner side of the front of the thigh in the first and second lumbar segments. (I think it possible from results in stroking the calf that the Gordon reflex may be a skin reflex.) From this rather wide distribution in the spinal cord it is evidently possible to reach the anterior horn cells of the fifth lumbar segment. Such an ending for branches of the neurones conducting centripetal impulses is indeed possible if we accept the histological pictures of our Golgi and Marchi preparations. In the former, both ascending and descending limbs of primary sensory neurones are found embracing several segments, and in the latter degeneration in the posterior columns, both above and below the level of the severed posterior root, is found.

The combination of these reflexes if they have been correctly interpreted, furnishes an interesting clinical demonstration of the anatomical and pathological findings.

## NÆVUS PILOSUS PIGMENTOSUS AND OTHER SKIN LESIONS TREATED WITH LIQUID AIR.*

By WILLIAM B. TRIMBLE, M D.,
NEW YORK.

INSTRUCTOR IN CLINICAL SURGERY, NEW YORK UNIVERSITY (UNIVERSITY AND BELLEVUE), CHIEF OF COLLEGE CLINIC, ASSISTANT AT THE NEW YORK SKIN AND CANCER HOSPITAL.

THINKING that it might be of some interest to the profession at large, and especially so to the dermatologist, it has occurred to me that a report of ten or twelve cases of various skin lesions treated with liquid air would not be inopportune. These clinical experiments and observations were made by me, with the assistance of the house surgeon (Dr. Mook) at the New York Skin and Cancer Hospital, in the clinic of Dr. George Henry Fox. During the past year so many nævi, especially the hairy mole variety, have come under my observation, that it was determined to make again some scientific attempt to remove these unsightly blemishes; and if they could not be wholly eradicated, to try, at least, to improve the appearance of the patients suffering therefrom. We have run the gamut, as have most other dermatologists, in an attempt to find a cure for this strange congenital condition, which is almost as great a bugbear to the dermatologist as cleft palate is to the surgeon. Electrolysis, caustics (carbolic, nitric, and trichloracetic acids), injections of alcohol, excision, etc., etc., have all been used; some sporadic cures have been effected in mild cases with each of the above mentioned remedies, but nothing that has gone

* Cases shown before the New York Dermatological and Genito-Urinary Society.

before seems to compare to or approximate the treatment under consideration.

Being greatly interested in similar experiments going on elsewhere, it was decided to put a certain number of selected cases under this plan of treatment, and through the courtesy of Dr. A. C. White, an afternoon's supply of liquid air was obtained once a week. For the benefit of those who may not have read the various scientific articles on liquid air, of several years ago, I will quote briefly, telling what it is, and some of its physical characteristics.

Liquid air is the common air we breathe, very much reduced in temperature. It liquifies at 312° F. below zero. We can readily understand how cold it must be, when we are told that it is about 400° colder than the ordinary atmosphere air. The composition of the normal air is 77 parts of nitrogen to 23 of oxygen, with a small quantity of carbon dioxide. Practically the same proportion exists when the gases are liquified. To the eye, the liquid seems to be boiling, giving off fumes similar to those of nitric acid. It is slightly opalescent in color, and to the touch it feels very cold and dry, giving a sensation of tingling. It evaporates rapidly, consequently it can be kept but a short time. We have been unable to keep it at the hospital more than two days. Its method of transportation seems to be a great stumbling block, as it will explode if corked up tightly; therefore a small hole is always left in the stopper, from which evaporation goes on. It is transported, at the present time, in a glass bulb; within the larger bulb is a smaller one; the intervening space between the two is a vacuum. This is called a "Dewar" bulb.

The method of application is either by the spray or swab, and the latter method was used on all the patients whose histories are given. A long white pine or orangewood stick, with a piece of absorbent cotton twisted around the end, is all that is necessary. A small, firm pledget of cotton, grasped in a volsellum forceps can be used if preferred. This is dipped in the liquid until the cotton is thoroughly saturated, the excess being allowed to drop off before it is applied.

The applications were made once each week, this being frequent enough in my opinion; and it subsequently proved to be sufficient in some of the cases, a longer interval was necessary, on account of the inflammation set up. The amount of pressure exerted at each application has given us some food for thought, and is one of the important points connected with the treatment. It varies, of course, with the amount of reaction desired by the surgeon.

For convenience of description, I will divide it into three arbitrary degrees, light, medium, and hard pressure. Light pressure causes a slight reaction and inflammation, all that is needed in some instances (erythematous lupus, for example). Medium pressure will cause a superficial slough; this medium pressure is the kind called for in the hairy mole. Hard pressure will cause a deep slough (sometimes used on an epithelioma).

The degree of reaction desired is left entirely to the operator, and "just how hard to press" is acquired only by observation and practice. The process is one of freezing; it renders the tissues extremely hard, so hard, in fact, that when tapped lightly with the reverse end of the stick, a sound is produced as if a pine board had been struck.

The pathological condition produced is of two kinds: a light application produces an anemia, followed very soon by a localized congestion; if medium or hard pressure is exerted on the tissues, an obliterating endarteritis is brought about with a consequent slough.

A certain amount of scarring has followed in most of these cases; however, the results have been extremely satisfactory, and a cosmetic effect has been produced far superior to the original lesion. Very little, if any, scarring takes place if the treatments are made infrequently and over a long period of time, provided the first degree of pressure is used; this naturally is the happiest result that can be obtained, as regards both the patient and the surgeon.

The liquid acts as a local anesthetic, and therefore causes no pain; the only sensation is one of slight tingling and burning. During the evaporation of liquid air, the nitrogen is given off much more quickly than the oxygen; consequently, after a few moments, the liquid is rich in oxygen; this has suggested the question as to whether the almost pure oxygen does not have some beneficial influence on the tissues. I must say that the liquid air has a marvelously fine effect on some of the chronic skin lesions, and the investigations at the Hospital will be continued by Dr. J. Francis Aitkin and myself.

Case I.—Nævus Pilosus Pigmentosis. A. F., boy, aged 11. The lesion was situated on the left upper eyelid, extending slightly beyond the outer canthus. It was brown, very hairy, darkly pigmented, resembling greatly the skin of a mouse; 1½ inches long, ½ inch wide, and with edges sharply circumscribed. About 12 applications of liquid air were made. Some edema of the eyelid and a rather profuse amount of lacrymation followed the applications. The hair began to disappear after the fourth treatment; ulceration commenced and a scab formed. Healing took place under the scab, leaving a clean and practically normal skin.

Case II.—Nævus Pilosus Pigmentosus. E. E., girl, aged 5. The lesion was situated on the left cheek, just to one side of the left angle of the mouth; about the size of a twenty-five cent piece; deeply pigmented, covered with hair, mouse-skin variety. Liquid air was applied about six times; a great deal of inflammation followed the last treatment, but the case progressed favorably; there was some slight scarring, but a fine result.

Case III.—Nævus Pilosus Pigmentosus. A. F., girl, aged 16. The lesion was situated on the right side of the nose; ¾ inch long, ½ inch wide; covered with long brown hair, mouse-skin variety. Seven applications were made; the hair entirely disappeared and nearly all the pigmentation; there remained a healthy scar, very slightly pigmented at one point; good result.

Case IV.—Nævus Pilosus Pigmentosus. R. K., girl, aged 6. The lesion was situated on the right temple just beyond the outer canthus of the right eye, pigmented as in the above cases. Three applications of liquid air resulted in a cure. There was a smooth white scar, hardly noticeable, except on close inspection.

Case V.—Nævus Pilosus Pigmentosus. C. R., woman, aged 24. The lesion was situated on the lower part of the left cheek, just to one side of the left angle of the mouth; pigmented and covered with thick reddish brown hairs; same kind as in the above cases; size of a twenty-five cent piece. Five applications of the liquid were made. The lesion healed with the exception of a small spot in the center, which still contains some hairs. The result bids fair to be as good as in the other cases. The patient is still under treatment.

Case VI.—Nævus Vasculosus (strawberry mark). S. R., girl, aged 12. The lesion was situated on the nose; it was the size of a large bean. This patient received five treatments and seemed to be improving when she disappeared, not having returned to the hospital after the last application was made.

Case VII.—Nævus Vasculosus (strawberry mark). M. R., woman, aged 35. The lesion was situated on the right temple, very close to the ear; size irregular, about 1¼ inches by ¾ inch. About six applications have been made at intervals of two weeks on account of the inflammation set up; quite a marked improvement up to the present time. Case still under treatment.

Case VIII.—Epithelioma. M. T., woman, aged 46. The growth was situated on the right side of the nose about ½ inch from the inner canthus of the eye; size of a large pea or bean; edges slightly raised; waxy indurated border; base red and scaly. Had been treated with ointments for a long time. Two treatments; first application caused a slight redness; second application caused the formation of a small crust, which subsequently fell off, leaving a smooth white scar.

Case IX.—Epithelioma. S. O., woman, aged 57. The growth was situated on the lower lip, near the angle of the mouth; it started as a small papule three years ago; became crusted and the crust fell off several times in succession, the lesion growing larger in the meanwhile. In September, 1904, it was about the size of a ten-cent piece, and very much indurated. Had received twenty *x*-ray exposures, resulting in a supposed cure, but a relapse occurred in September, 1905. One application of liquid air on September 26. Result, cure.

Case X.—Lupus erythematosus. S. C., woman, aged 45. Duration of disease 2½ years. There were lesions on both cheeks near the ears, and a small one on the forehead. Liquid air was applied on the right cheek only; other treatment on the left side. The lesion on the right cheek healed rapidly with three or four applications of liquid air.

Case XI.—Lupus erythematosus. R. A., woman, aged 30. A patch of this disease, about the size of a silver dollar, was situated on left cheek, high up. The patient has had three treatments with marked improvement; is still under treatment.

There does not seem to be any doubt about the beneficial effect of liquid air in cases of epithelioma, lupus, and nævus pilosus pigmentosus. In cases of nævus vasculosus, there is slight improvement; insufficient experience, as yet, prevents a more definite statement.

56 East Twenty-fifth Street.

**Why We Are Sometimes Obliged to Reoperate in Gallstone Cases.**—James E. Moore declares that the various conditions which require a second operation are fistula, stones that have been overlooked at the first operation, adhesions, cholecystitis, and the reformation of stones. Since it has been the custom to attach the gall-bladder to the peritoneum, biliary fistulæ have been rare. As a rule, when fistula remains now, it is due to obstruction of a duct by a stone or stricture. The larger number of secondary operations are for the removal of stones which were left at the first operation. No gallstone operation is complete without a thorough examination of the cystic, common, and hepatic ducts. A finger should explore the gall-bladder. A thumb and finger should then palpate the whole course of the ducts from the peritoneal side. Probes are fallible. As a rule, after removal of the stones, adhesions disappear. Certain gall-bladders become inflamed, and require an operation even after the stones have been removed. The writer does not believe that the view that recurrence of stones rarely if ever occurs, is rational. There can be nothing to hinder the entrance of bacteria into the gall-bladder a second time. Stones recur in the kidney and bladder, and it seems as probable that they may recur in the gall-bladder.—*Northwestern Lancet.*

**A New Radical Operation for Large Femoral Hernias.**—Polya says that none of the methods occluding the femoral thus far in use is very effectual in cases in which the canal is very large. He describes a procedure in which the hernial orifice is plugged with the proximal stump of the sartorius muscle, which is cut across for this purpose. The steps of the operation are as follows: A T-shaped or L-shaped incision is made over the hernial site and the skin flaps are dissected back. The saphenous vein is tied off and cut away, the sac is tied off as high as possible and the stump buried. The sheath of the sartorius is then incised from the middle of the anterior superior spine of the ilium to the middle of the thigh. The muscle is cut across and the proximal stump is drawn through an opening in its posterior sheath and stuffed into the femoral canal as deeply as possible. It is then sutured to the pectorical fascia, and to the ligaments of Cowper, Gimbernot and Poupart. The burial of the muscle is completed by several heavy sutures passing through Poupart's ligament, the sartorius stump and the pectorical fascia. A wide flap of fascia lota is dissected up and reflected over the femoral ring and is sutured to the neighboring structures so as completely to cover the site of operation. Finally the skin incision is closed. The author has treated two cases by this method, one with prompt recovery, and at the autopsy of the second patient, who died of erysipelas some time later, it was found that firm healing of all the layers had occurred so that peritoneal protrusion was impossible. He recommends the method only for severe cases, however.—*Zentralblatt für Chirurgie.*

**Organized Water as a Food.**—John Uri Lloyd first discusses molecular water, which in both crystal and colloid tissues is capable of expulsion by dessication. He then suggests that water may be combined in an untold number of liquid organic structures that are as yet invisible, uncrystallizable, and beyond the reach of our senses as organized bodies. He declares that water supports life, governs life, nourishes life, feeds all structures, and constitutes the larger share of all organic tissues. It seems strange that it should be viewed as a carrier of something else only. The writer further suggests that the vitalized water of organized water-bearing foods, and the combined water of such foods as carbohydrates and fats, are the foundations of the real foods for tissues, affiliating other materials, such as nitrogen, carbon, and hydrogen, which are subject to the dominating agent, water. Organic structures may, some time, be defined as products of the migration of the water molecule. It may be that a closer inquiry into the water molecule, the vitalized or easily vitalized water molecule and its many shadings will open up a field for the construction of more rational food products.—*Pacific Medical Journal.*

**An Unusual Wound of the Diaphragm.**—Muscatello presented to the Medicochirurgical Society of Parma a patient who had recovered from a very unusual wound. He had received a knife thrust in the side, corresponding with the lower margin of the ninth rib on the right, in the anterior axillary line, and the omentum had become prolapsed. The knife had made a large wound in the eighth costal space, had severed the ninth cartilage, and cut the diaphragm to the extent of 9 centimeters. The rib had evidently diverted the knife from its course, so that the penetration had been slight, and the viscera had not been wounded. The omentum was resected, and the wound closed with thirteen sutures. The diaphragm was sutured through the pleural surface. The literature contains 27 cases of transpleural suture of the diaphragm.—*La Riforma Medicc.*

**Gangrenous Prolapsed Hemorrhoids.**—Baracz is in favor of immediate radical operation in this condition. The bowels are cleared with castor oil and the sphincter is well dilated under deep anesthesia. The gangrenous hemorrhoids are clamped as far as possible from the necrotic area, and destroyed with the actual cautery. The bowels are opened on the sixth or seventd day.—*Zentralblatt f. Chirurgie.*

## "CARBONACIDEMIA."

THE past few decades have been enriched by many discoveries dealing with the extraneous causes of disease, while the study of the internal factors has unfortunately suffered in its development. During the seventies and early eighties, physiology had begun to exert a favorable influence on both pathology and therapeutics, but then the advances made in the study of the various pathogenic microorganisms occupied the attention to such an extent that it became difficult for investigators in opposing lines of thought to gain even a hearing. And now the pendulum has been swinging back again, and physiological pathology—if we may call it thus—is again being cultivated. One result of this will undoubtedly be that the production of fads will be stimulated, for it will be an easy matter to attribute this or that obscure complaint to the presence in the body of some substance less easy of demonstration than a bacterium or plasmodium.

We have heard a great deal lately about autointoxications of various kinds, due to the retention in the system of the weaker acids in abnormal amounts. Renewed interest has been generated in the uric acid theory by the recent publications of Haig, the absorption of toxic products other than bacterial from the intestinal canal is occupying the attention of numerous investigators, and now we are finally being made acquainted with the fact that an excess of carbonic acid in the tissues may be an important factor in the etiology of many diseased conditions. An interesting contribution to this subject has recently been made by Lahmann of Dresden, who designates this abnormal retention as "carbonacidemia," or "carbonacidosis." In order to appreciate his theory it will be necessary to review certain facts in respiratory physiology. It is a matter of common observation that on awakening in the morning, respiration becomes accelerated and deepened, with a corresponding increase in the amount of carbonic acid gas eliminated. During the course of the forenoon, the latter becomes reduced until at the time of the mid-day meal a renewed acceleration takes place, to be followed in the afternoon by a second decline and a somewhat slighter rise after the evening meal. If, therefore, the excretion of $CO_2$ is increased during the morning hours and remains stationary in spite of the ordinary muscular and cerebral activity, or, in fact, is diminished, this furnishes strong ground for the belief that during the night there occurs a retention of carbonic acid in the blood and in the tissues. To this phenomenon, Lahmann applies the term physiological nocturnal carbonacidemia.

The sodium content of the body is the important neutralizing agent for the acids in the system, and the excretion of these, particularly uric acid, is entirely dependent upon the amount of sodium which remains uncombined with $CO_2$. An abnormal quantity of the latter therefore means a reduction of the sodium in the blood and a consequent interference with the excretion of uric acid. As the $CO_2$ is mostly gotten rid of during early morning hours, it will be seen that a greater poportion of free alkalies is available for the uric acid and allied substances, so that in this manner the increased excretion of uric acid which has been found to occur during the early morning is apparently accounted for. The physiological retention of carbonic acid in the system has thus the effect of causing a retention of uric and other autotoxic weak acids. Furthermore, the abnormally high $CO_2$ in the tissues affects the various nerve centers and a narcotic effect is produced by this less oxygenated blood. But before this becomes manifest, that is, during the early morning, when the $CO_2$ excretion is at the minimum, the slower heart action of the earlier parts of the night has already brought about a diminished arterial pressure, with a consequent lessening of the peripheral circulation and a compensatory filling of the internal organs. Among the other effects of this saturation with $CO_2$ is a vasomotor constriction of the peripheral capillary vessels, and here the writer thinks that a transition from a physiological to a pathological condition is readily possible. It is interesting to read how he accounts for the production of many ailments by assuming that they are due at least in part to circulatory states brought about by this oversaturation of the blood with carbonic acid. Women are especially prone to these disturbances, because they present normally a less active $CO_2$ excretion, and in the treatment of these disturbances in women who are languid and apparently weak no attention should be paid to these characteristics. On the contrary, instead of being pampered and cuddled, active exercise is the best means to overcome this false fatigue, and a rest cure should always be alternated with periods of activity.

The field which is opened up by this theory is very extensive and can be made to include almost all the internal diseases which are not known to be due to bacterial, parasitic, or other toxic causes. If we apply it to treatment, the main indication appears to consist in means for stimulating the respiratory center, so that the excess of carbonic acid may be gotten rid of through the medium of the lungs. Lahmann claims that in many hydriatic procedures the good results are as much due to reflex stimulation of the respiratory center as to any direct effect on the vasomotor system. The most satisfactory means of obtaining the desired end he has found to be the open-air bath, and in the large number of cases in which he has applied it the results have always been well marked and permanent. It is also advisable in most instances to supplement this by appropriate treatment with alkalies.

If further observations bear out the facts cited in Dr. Lahmann's pamphlet, an important advance in therapeutics will doubtless have been gained. It is curious to note, however, the sudden appearance of the carbon theory of gout and other diseases. In an article in the MEDICAL RECORD of June 17, Francis Hare argued plausibly in favor of "hyperpyremia," as he calls the hypothetical accumulations of carbonaceous material in the blood; and at the

conclusion of a paper on the use of formic acid in the treatment of rheumatic conditions, in the following issue, Couch asserts that one of the most prolific causes of disease is the presence of carbonic acid in the blood—the "carbonacidemia" of Lahmann.

## THE THERAPEUTIC VALUE OF COLORS.

A STUDY of the effects of color upon the minds of those diseased, as well as of those in health, would open up a very interesting field. That color effects may be therapeutically beneficial or otherwise, does not seem to be appreciated by either the medical man or the artist. When we are seeking for methods that will prove helpful in diseases, we should take advantage of anything which promises even a small measure of success, more especially when it can be so readily applied in connection with other means to aid, to maintain, or restore the sanitary equilibrium of man.

The impressions that different colored furnishings make upon persons, if studied and utilized, might be of value in many conditions, especially in disturbed mental states. The sensation that one experiences upon entering a room, which is largely due to the blending of colors used in the decorations, is perhaps unconsciously felt, but yet it often makes itself apparent in determining the mental condition of the visitor. It is not alone the sanctity of place which affords a peaceful sense of repose on entering the cathedral or church. The effect of the harmonizing lights from the stained glass windows influences largely in this feeling of repose of body and mind. Then the exhilaration experienced when viewing the panorama of a landscape in autumn when the variegated colored foliage is in evidence, the restful gray at the close of day, and the gorgeous display of color effects at sunset, are always in evidence.

Colors symbolize the emotions, and these are depressing or uplifting. Black represents death, sorrow, the close of day, night, and the tomb. These last are dark and still, while death is the going out of the light of life. Red is the symbol of joy in all oriental countries, and has been so from prehistoric times. We have the red at sunrise, the birth of day and the reappearance of life. The young and healthy are of ruddy complexions, while the perfected fruit is often red. Yellow belongs to the autumn of life—"the seer and yellow" to the sunset, or close of day or life. White symbolizes innocence and purity.

Red may appear to one a violent color, therefore, a disturbing one; while to another, it may prove soothing. Yellow, or yellow and green, white and gald, pale blue and silver, will be colors which appeal to some. The decoration of interiors of dwellings, offices, and public places, such as churches, theaters, lyceums, etc., should be made a careful study for its various color effects not only upon the individual but upon the masses. How much the somber coloring used in decorating the dining room influences digestion as against the cheerful blending of color effects should be studied and determined. Iodosyncrasies of those who are to occupy residences, or in the case of invalids who must remain in one room for a long time, probably for weeks or months, should be carefully studied in selecting the colors for decorations. In nervous and mental conditions the judicious choice of color effects in decorations will doubtless prove highly beneficial. It would be interesting to learn the results of experiments made along these lines.

## TUMOR GROWTH IN ITS REFERENCE TO THE CAUSATION OF DISEASE.

DR. JOHN CHIENE publishes in the *Edinburgh Medical Journal* for June his introductory lecture to the class of operative surgery in the University of Edinburgh, April, 1905. The lecture deals with the causation of disease with special reference to tumor growth. Referring to the reproductive action inherent in the human cell, Dr. Chiene quotes what he said on that subject in 1896. "Our bodies are made up of these cells, and there is going on within us the double process of nutrition and reproduction, which is in every particular the prototype of the processes of nutrition and reproduction as we see them in the higher animals and in man, with all the physical forces in full play, so closely associated with these two great manifestations of life. In each cell we have, possibly, the father side (the paternal), with its outcomes, strength, courage, endurance, self-reliance; and the mother side (the maternal) with its outcomes, tenderness, gentleness, unselfishness, and self-sacrifice." The terms "maternal" and "paternal," thinks the writer, may be modified probably after puberty, as to the acquirements of the individual from surroundings and from himself by two important organs, the testicle and ovary; in their essence, however, they are derived from our ancestors. Thus Dr. Chiene argues that if the ancestral —maternal and paternal—elements can be modified by the testicle and ovary, we are justified in assuming that we may modify the maternal and paternal by therapeutic means. In a few words, if the maternal and paternal elements become unbalanced, producing disease, cannot the balance be restored, and may not the hidden functions of the reproductive cells be of use to us in an attempt to explain the causation of disease?

With regard to the causation of tumor growth, the writer postulates that in the consideration of the life history of anything living we must consider (1) its tissues, (2) its surroundings, and (3) its adaptation to these surroundings. According to Dr. Chiene a tumor starts because of a want of balance in the two elements (paternal and maternal) in the cell, and it continues growing because that want of balance is present in the surrounding cells, or in the fluid by which the cells are bathed, that is, in the cell food. The abnormal agent acts when the two elements in the tissues have lost their balance.

Early uncontrolled maternity is, in the opinion of the writer, the essence of malignant tumor, and the cells of a person predisposed to tumor growth have the maternal element in a marked degree. Dr. Chiene thinks that too many investigators are spending their time in searching for the "abnormal agent" when they might be better employed in devoting their energies to the study of the question: Why is the cell fertile to an abnormal agent?

## THE DIAGNOSTIC VALUE AND THE THERAPEUTIC EFFECTS OF LUMBAR PUNCTURE.

LITTLE precise knowledge exists concerning the degree of pressure under which the cerebrospinal fluid is contained within the membranes and cavities of the brain and cord, both during health and in conditions of disease. Likewise the indications for and the limitations of lumbar puncture, both as a diagnostic procedure and as a therapeutic measure, have not

been as yet clearly defined. A means to this desired end is afforded by a simple and ingenious instrument devised by Dr. Frank C. Eve (*Lancet*, April 22, 1905). It consists of a lumbar puncture needle with a detachable handle, and adapted on the one hand to a vertical graduated glass tube and on the other to an exit tube closed by means of a spring clip. The apparatus is sterilized by boiling just before being used. The patient lies on one side with the knees drawn up and the back arched, the head and spinal column being approximately horizontal. After the skin has been carefully cleansed, the needle is introduced at the level of the iliac crests one-half inch below and external to the spinous process of a vertebra. The pressure can be read off as the cerebrospinal fluid runs up the manometer tubing. By clamping the manometer tube and removing the clamp of the exit tube fluid can be obtained for study. From an ounce to an ounce and a half of fluid can be permitted to escape for the relief of pressure. As a result of observations made in some 50 clinical cases with the instrument described Eve believes that the therapeutic effects of lumbar puncture are often greater than is generally believed. The good effects are to be attributed to the relief of excessive tension, irrigation of the brain by fresh fluid secreted in place of that withdrawn, temporary cerebral hyperemia resulting from dilatation of the blood vessels to take the place of the fluid withdrawn until a new supply is secreted, or, conversely, arrest of cerebral anemia due to excessive intracranial pressure and a substantial change of cerebral environment, of which nature may sometimes be able to take advantage. From a diagnostic standpoint the withdrawal of pink fluid is indicative of cerebral hemorrhage, fracture of the skull with injury to the dura mater, or severe superficial cerebral laceration with rupture of the pia mater. The development of a faint spider's web clot after the fluid has stood for several hours points strongly to meningitis. Cytological, bacteriological, and inoculation studies may afford important diagnostic aid. Occlusion of the cerebral from the spinal cavities from the presence of a tumor or of hydrocephalus may be recognized from failure to obtain fluid. Lumbar puncture may be justifiable in cases of cerebral hemorrhage when the pressure is high, provided the reduction in pressure be made slowly to one-half and not too soon after the occurrence of the bleeding. The treatment should not be employed without the use of a manometer. Experience in one case suggested the possible existence of a disease in the cerebrospinal cavity analogous to glaucoma in the ocular cavity, that is a disease of high pressure due to obstructed outflow of secretion. Surprisingly good results were obtained from lumbar puncture in cases of fracture at the base of the skull, cerebral concussion, post-traumatic cerebral disturbance, cerebral thrombosis, severe chorea, uremic coma and optic neuritis, anomalous ataxia, and tuberculous meningitis.

### Cerebrospinal Meningitis in Europe.

Cerebrospinal meningitis has been as prevalent in certain parts of Europe during the past few months as in New York. In Germany cases have occurred in all parts, while in Silesia an epidemic of the disease has been raging. The *Edinburgh Medical Journal* of June, referring to the matter editorially, notes that the Prussian authorities have distributed information and advice in regard to the disease amongst the medical profession and the general public. The editorial in question also advances the opinion that in Great Britain its presence may be expected at any time in an epidemic form, and suggests that the English Local Government Board adopt the same action as it adopted with such marked success when there was a threatened invasion of cholera, and more recently of plague, namely, sending circulars of advice to local authorities. It may be hoped that the New York Commission will unravel some of the many unknown features of cerebrospinal meningitis, for at present there is no disease concerning which less is known, and consequently the means of prevention and treatment are unsatisfactory in the extreme. Until something more is learned of the disease, circulars of advice are of little more value than blank paper.

## News of the Week.

**Lodge Practice in California.**—In obedience to a resolution that was passed by the judicial council of the California State Medical Society at its recent meeting, the Secretary of the Society has sent a circular letter to the various societies in affiliation, asking an expression of opinion in regard to lodge practice. An almost immediate result has been the passage by several of the societies, of resolutions to amend their by-laws in such manner as to exclude from membership all physicians who are "guilty" of engaging in lodge practice. In a few instances it has been forbidden also to make life insurance examinations for less than $5 each. Some of the societies, however, long ago refused membership to lodge doctors.

**The Pure Food Movement.**—An organization known as the National Food Manufacturers' Association, with headquarters in Chicago, has been formed for the purpose of protecting "the legitimate manufacturers of food and food products and the consumer against adulterated, fraudulent, and unwholesome food." Dr. Harvey W. Wiley, chief of the Bureau of Chemistry, has gone to Europe under instructions from Secretary Wilson to make an exhaustive investigation of methods of preparing and preserving food products for shipment to America. He will visit all of the leading cities of Europe which have an export food trade with the United States and will be gone until the middle of September. The policy is to have a more rigid inspection of foods. Upon his return laboratories will be established in Boston, Philadelphia, New Orleans, and Chicago. At present the only inspection laboratories are in New York, San Francisco, and Washington.

**A Circular of Instruction Regarding Mosquito Extermination.**—A four-page circular setting forth the causes and prevention of mosquito incubation, which has been prepared by Dr. A. H. Doty, Health Officer of the Port of New York, has been issued by the Board of Health. A copy will be mailed to every family on Staten Island in the hope that they will learn from it the simple means of preventing mosquito propagation. The circular explains in detail the great variety of places where mosquitos may hatch. A paragraph is devoted to the methods of proper draining and the economical use of crude oil.

**Laying of Corner Stone of Michael Reese Hospital.**—The corner stone of the new building being erected by the Michael Reese Hospital will be laid on July 4 by Herman F. Hahn, chairman of the Hospital Committee. An address will be delivered by Governor Deneen. This new hospital, which will cost approximately $500,000, will be completed next May. It is to be six stories high, and equipped with the most approved heating, lighting, and ventilation systems. There will be accommodations for 240 beds,

including 60 private rooms. There are to be three operation rooms, and special provisions for isolating patients in the surgical, medical, gynecological, and maternity departments. The children's building, for both pay and charity patients, will be separate from the main buildings, and will have an entrance from the outside.

**A Fatal Impulse.**—An indigent Hebrew who had been treated at one of the city hospitals recently complained that while there the word "Fakir" was branded on his chest. On investigation it appeared that he was being treated for neuralgic pains in the chest with the thermocautery, and that while one interne was making the application, another doctor entered the room and remarked that the man was a fakir. In response to an unconscious impulse, as he alleges, the manipulator of the cautery traced the letters in question on the man's skin, an act for which he was summarily dismissed from his position on the house staff. According to one newspaper account of this affair, the thermocautery is an instrument by means of which particles of benzine are injected under the skin and ignited by an electric spark.

**A State Society for Colored Physicians in Virginia.**—At a meeting of colored physicians in Richmond on June 26, a State medical association, to be known as the Old Dominion Medical and Surgical Society was organized. The following officers were elected: *President,* Dr. Charles R. Alexander, Petersburg; *Vice-Presidents,* Drs. W. E. Atkins, Hampton, R. J. Boland, Roanoke, and Albert Johnson, Alexandria; *Journalist,* Dr. E. R. Jefferson, Richmond; *Recording Secretary,* Dr. A. W. G. Farrar, Richmond; *Corresponding Secretary,* Dr. H. L. Harris, Richmond; *Treasurer,* Dr. R. E. Jones, Richmond.

**Public Health Matters in Chicago.**—The hospital population in Chicago (1,798) was lower on July 1 than at any time since last November. The only disquieting feature in this indicator of the state of the public health is an increase of the typhoid fever contingent, unusual at this season of the year and due, probably, to the poor quality of the public water supply during the past two months. Excepting smallpox, all the other contagious and infectious diseases show a decrease in the number of cases reported—diphtheria most marked, 28 cases during the week, as against 36 the week before. There were 18 cases of smallpox discovered, as against 15 during the week of June 17.

**Decrease of Typhoid Fever in Philadelphia.**—For the week ending July 1, 82 new cases of typhoid fever were reported, as compared with 146 cases for the preceding week. The majority again occurred in wards receiving their water supply directly from the Delaware River. Not a single case was reported from the Twenty-first and Twenty-second Wards, both of which are supplied with filtered water.

**A New Superintendent for Bellevue Hospital.**—Eighteen candidates appeared to take the civil service examination held for the purpose of selecting a new general superintendent for Bellevue Hospital. The Municipal Civil Service Commission will send the list of applicants who received the highest rating to the Board of Trustees of Bellevue and Allied Hospitals, and the trustees will select a new superintendent from the lot. The salary is $6,000 a year.

**Site for City Sanatorium.**—Health Commissioner Darlington has secured permission from the local authorities for the location of the city's sanatorium for tuberculous patients in the towns of Greenville and Mount Hope, Orange County. Options have been secured on several thousand acres of land and the establishment of the sanatorium now seems certain.

**Lower Death-rate in Philadelphia.**—For the week ended July 1 there were reported to the Philadelphia Bureau of Health 441 deaths, as compared with 451 during the preceding week, and 533 during the corresponding week of the previous year. One hundred and forty-eight of the number occurred in children under the age of five years.

**The Medical Society of the State of California** has been incorporated for the purpose, as stated in the articles of incorporation, of unifying the interests of the physicians and surgeons of the State and to establish and maintain free clinics and dispensaries for the treatment of the sick poor. The Board of Directors is composed of the following physicians: Drs. A. G. Dardarff, George G. Gere, W. A. Harvey, H. W. Hunsaker, and C. P. Higgins.

**Bequests to Hospital.**—By the will of the late John L. Devereux of Philadelphia, the Polyclinic Hospital, the Episcopal Hospital, and the Home for Crippled Children have each received $3,562.

**Yellow Fever at the Isthmus.**—The cabled reports from Panama show that during the month of May there were six deaths from yellow fever, and during the month of June ten more. Only six of these were canal employees, though the working force on the Isthmus numbers nearly 10,000.

**A Guillotine Experiment.**—At a recent public execution at Orleans, the doctor in attendance seized the prisoner's head as it fell in the basket and shouted the man's name in the ear, whereupon, it is said, the eyes opened slowly and then closed. The same response was elicited a second time, but a third call was without effect. The incident, if authentic, affords an interesting demonstration of the persistence of reflex nervous excitability.

**$17,000 for War Against Mosquitos.**—The Board of Estimates has made an appropriation of $17,000 to enable the Health Board to prosecute its campaign against the mosquitos on Staten Island.

**Kansas University to Give Medical Course.**—Beginning September 6, 1905, the University of Kansas will give, for the first time, a full course leading to the degree of M.D.

**Wayne County (Mich.) Medical Society.**—At the recent meeting of this society, held in Detroit, the following officers were elected: *President,* Dr. S. H. Knight; *Vice-President,* Dr. E. J. Kendall; *Secretary and Treasurer,* Fred Thompson.

**Dr. Edward H. Shields** has been elected professor of skin and venereal diseases at the Miami Medical College, Cincinnati.

**Dr. Samuel Iglauer** has been elected associate professor of laryngology to the Ohio Medical College, Cincinnati.

**Chicago Emergency Hospital.**—This new hospital was opened on June 27. It is located at 309 Fifth Avenue. The surgeon-in-chief is Dr. Richard M. Fletcher.

**Jenner Medical College Commencement Exercises.**—This college also held its graduation exercises, and 15 degrees were given. Dr. Stuart Johnstone delivered the address, and Dr. John D. MacKellar was class valedictorian.

**New Free Clinic for Tuberculosis.**—A free clinic for tuberculosis patients has been established at the Cincinnati Polyclinic by the local branch of the National Antituberculosis Society. Drs. B. F. Lyle, J. H. Schröder, and Iliff will be in charge.

**Obituary Notes.**—Dr. William Leavitt Jackson of Roxbury, Mass., died at Nanheim, Germany, on June 22, at the age of 52 years. He was born in Gardner, Me., and was graduated from the Harvard Medical School in 1876.

Dr. W. C. Barnes of Marion, Ind., died June 20, of apoplexy, at the age of 58 years. He was born near Jalapa, Ind., and was graduated from the Medical College of Indiana in the class of 1874.

Dr. Richard M. Fletcher died June 10 at his home in Madison, Ala., at the age of 74 years. He was graduated from the Medical Department of the University of Pennsylvania in 1854. He was a surgeon in the Confederate army during the civil war.

Dr. John B. Enright of Louisville, died on June 20. He was born in Kentucky, and was graduated from the Medical Department of the University of Louisville in 1885. He was for a number of years demonstrator and then professor of anatomy in the Kentucky School of Medicine.

Dr. Daniel P. Neihart died at his home in Nebraska City, Neb., on June 18, at the age of 83 years. He was born in Germany, and received his degree of M.D. at Heidelberg in 1850.

Dr. Charles E. Francis, formerly one of the leading dentists of this city, but retired for the last four years, died July 2 in Stamford, Conn. He was born in Hartford in 1827. He was one of the founders of the New York Dental College, and was for many years president of the Dental Society of New York.

## Correspondence.

### OUR LONDON LETTER.

(From Our Special Correspondent.)

ARMY REPORT—HOSPITAL SUNDAY—IMMUNE AREAS—ANTIS—FEEBLE-MINDED—ECTOPIC GESTATION—THYROID-LIKE STRUCTURES—DEFORMED FETUS—PRIMARY CANCER OF FALLOPIAN TUBES—ABDOMINAL TUBERCULOSIS IN CHILDHOOD—OBITUARIES.

London, June 16, 1905.

The Report of the Army Medical Department for the year 1903 was issued on Saturday. The admissions to hospital during that year represented a ratio of 758.1 per 1,000 of the strength, and the deaths 7.13 on a strength (including detached men not shown in the returns received) of 263,888. In 1902, the ratios were 751.9 and 7.52, and for the decennial period, 1893 to 1902, the corresponding ratios were 927.4 and 8.57. It is stated that these ratios compare favorably with other armies, and the death rate is not considered excessive.

Hospital Sunday is fixed for the 25th, and almost all the preparations are made. There is much hope of a better collection than last year, and general expressions that the London public requires considerable stimulation in this work.

We have had some important statements made of late respecting the immunity which Barbados enjoys from malaria. It is said that the anopheles is not found in the island. Sir P. Manson says an analogous local immunity is found in the Pacific Islands, where elephantiasis and filarial diseases prevail, but malaria in several of the islands is unknown. As it is hardly likely that the anopheles has never visited Barbados, it has been suggested that some agent which destroys it may be the cause of the immunity, and Mr. Kenrick Gibbons, a many years' resident, says there is a tiny fish which swarms in all the ponds and pools and is appropriately called "millions," which lives largely on the larvæ of mosquitos. But then, how is it the fish has not also exterminated the other mosquitos found in Barbados?

The various "antis" that flourish among us seem to have one common characteristic—they are mostly anti-truth. One scarcely knows how otherwise to account for the statements circulated. Among those lately sent to sensational papers is the assertion attributed to a "surgeon in the German army," that in 1888 when he was on duty at Strasburg there were over 2,000 cases of smallpox in one house." Our anti-vacs should explain how this staggering statement is to be reconciled with the official returns for 1888 of 184 cases in the whole German empire.

Dr. A. F. Fredgold, Research Scholar of the County Council, gave evidence before the Commission on the Feeble-Minded. He thought it theoretically correct to say that all patients suffering from mental defect in any degree should be subject to permanent detention, but, practically, he doubted the possibility of applying compulsory detention to the mildest grade of feeble-mindedness, though much might be done in the way of supervision.

The variations that have been observed in tubal gestation have often provoked comment. It has been followed by a pregnancy in the opposite tube, has been repeated on the same side, has occurred simultaneously in both tubes, in one tube and the uterus, and in a tubal stump after operation. Mr. Doran reported a case at the Obstetrical Society which had twice been under his care in hospital, with clinical evidence of tubal pregnancy first on the right side and a year later on the left. On account of increasing swelling, pain, and hemorrhage laparotomy was performed, and clots, with both tubes and the right ovary, were removed. The patient was phthisical and died thirteen months later. Mr. Doran said he had had three cases in which normal pregnancy had followed removal of a pregnant tube. The question might be asked whether it would be justifiable to remove the opposite tube when operating for tubal gestation, as a second abnormal pregnancy is evidently possible.

Dr. Boxall mentioned a case in which normal pregnancy and delivery occurred a year after removal of a ruptured tubal pregnancy.

Dr. H. R. Spencer said he had operated on three cases of bilateral tubal pregnancy, and in two others had observed uterine pregnancy after tubal.

Mrs. Scharleib mentioned a case of ectopic gestation operated on in July last and said the patient was now five months pregnant.

Lieut.-Col. Sturmer said the case which he lately reported to the Society, in which at the time of operation the opposite tube was red and swollen, but was not removed, ectopic pregnancy again occurred. He thought it would have been better to have removed both tubes.

In his reply, Mr. Doran remarked that the evidence supported the view that after removal of a tubal gestation if pregnancy occurred, it was usually normal, so that it was not justifiable to remove the other tube.

Dr. Russell Andrews related a case of ruptured interstitial pregnancy. The period was only six days overdue and the gestation cavity in the left corner only just admitted the point of his thumb. The uterus was removed by supravaginal amputation, both ovaries being left. He raised the question, whether in such cases, with so early rupture, the uterus might not be left, merely excising the affected corner and suturing the raw surfaces.

Mr. C. Singer exhibited a case of extreme ectopia vesicæ and absence of the colon in a full-time fetus which lived fourteen days.

Dr. Hamilton Bell reported two cases of multilocular cysts removed by operation, in which thyroid-like structures were formed. Having mentioned various possible explanations he accepted that of colloid degeneration of an ordinary cystic adenoma of the ovary. Dr. Williamson agreed that the appearance was brought about by pressure exerted by the colloid contents in the smaller loculi upon the columnar epithelium of an ovarian adenoma. But he thought it further possible that some cases were of a teratomatous origin.

Dr. Cullingworth exhibited and described specimens of primary carcinoma of both fallopian tubes from a woman of 41. The diagnosis was rather obscure, and after a month in bed without benefit operation was agreed to, as there had been such suffering for two years. On a preliminary enema being given, a pint of bright blood passed by the rectum, and under anesthesia a small fistulous opening was found four inches from the anus. On opening the abdomen malignant disease was seen to affect both tubes. No extension to other parts was felt. No ascites. The patient died suddenly eighty-four hours after operation. It was suggested that the cancer developed in an old hydrosalpinx.

Dr. Branson has read a paper at the Medico-Chi. on abdominal tuberculosis in childhood, founded on forty cases at the East London Hospital. An unaccountable loss of weight with irregularity of the bowels calls for careful examination under an anesthetic. Hard enlarged mesenteric glands and the tuberculin test are the only means of distinguishing the disease from simple gastroenteritis in an early stage. Later the diagnosis has to be made from cirrhosis of the liver and diffuse peritoneal sarcoma, both of which are rare in children. Palpation must be relied on to differentiate tuberculous peritonitis from simple gastroenteritis, the large glands in the latter disease being soft and impalpable. In six out of eleven fatal cases the disease was limited to the abdomen, and more frequent early operation was suggested.

Dr. Carr said the disease was practically unknown in the first year of life, and later improper feeding was concerned, although less milk was given, throwing doubt on its supposed origin from milk. He attributed some influence to the crawling habit of this period of life. Tuberculosis of the glands is not uncommon without intestinal infection.

Prognosis was better in acute ascitic cases, which he thought due sometimes to blood infection.

Dr. Sydney Phillips admitted tuberculosis of the peritoneum without primary intestinal infection. Parietal adhesions in these cases were not the only cause of intestinal obstruction. He had not seen ascitic fluid speedily absorbed, and the results of operation were favorable.

Mr. S. Paget thought the only surgical procedure should be incision or paracentesis. Attempts to resect the gut or remove the enlarged gland would end in the child's death.

Dr. A. E. Garrod commented on the great preponderance of thoracic over abdominal tuberculosis in infancy. In peritoneal cases the glands had failed to intercept the bacilli.

Mr. J. D. Malcolm remarked on the presence of calcareous glands found in abdominal sections performed on adults.

A number of recent deaths call for notice. Foremost, as one best known to me, the venerable Fred James Gant, F.R.C.S., 1861, M. 1849, for about half a century a prominent surgeon and teacher. He was at the Royal Free Hospital, at which the Woman's Medical School arranged for its clinical work. His "Science and Practice of Surgery," must be well known to you, for three editions were called for, as well as his "Principles of Surgery," which reached a fifth editon. His other surgical works and contributions were numerous. He had served as president of the Medical and vice-president of the Medical-Chirurgical Societies. Of late years he devoted himself to philosophical studies, the extent of which you may judge from some of the books he published, as "The Land of Humanity;" "Our Dead Selves to Higher Things," "Modern Natural Theology," the "Mystery of Suffering," and several other volumes, most of which arrived at successive editions. He passed away on Tuesday, the 6th inst.

Dr. Jas. St. John Gage Parsons died on the 2d inst. He took the membership of the College of Surgeons in 1843, the Fellowship in 1858, and the L.R.C.P. in 1859. He was engaged in the cholera epidemic at Bristol in 1859. The honorary M.D., of Chicago, was conferred on him in 1870. Besides contributions to the medical journals, he published a translation of the Proem of the Gospel of St. John with notes.

Dr. James Murphy, A.M., M.D.(Dub.), a leading surgeon and gynecologist in the North of England, died on the 30th ult., in his 52d year, of pneumonia. He was at work up to the 27th, so his illness was very short. He had been a lecturer in the Durham College since 1878. His last choice being "Medical Jurisprudence." He was surgeon to the Sunderland Infirmary and other hospitals, and contributed various papers on surgery and gynecology to the societies and journals. He was a great favorite with his colleagues and his pupils, a man of sterling character and generally trusted.

Dr. Emanuel May died on the 3d inst., in his 88th year. He took his early diplomas in 1839-40 and became M.D. (Heidelberg), and member of the College of Physicians in 1871. He wrote a work on Diphtheria (1889), and various contributions to the *Lancet*, etc.

Colonel Wm. Owen Wolseley, R.A.M.C., died on the 3d inst. He took the licenses of the Dublin Colleges of Physicians and Surgeons in 1879, and added the D.P.H. of Victoria University in 1893.

Surgeon-General John Warren, late of the army medical staff, died on the 4th inst., aged 70. M.R.C.S., 1856.

## OUR BERLIN LETTER.

(From Our Special Correspondent.)

THE RÖNTGEN CONGRESS—RADIODIAGNOSIS OF INTERNAL DISEASES—DETECTION OF RENAL CALCULI—X-RAY TREATMENT OF CANCER—RÖNTGEN RAYS FROM HIGH TENSION CURRENTS—EMPLOYMENT OF THE CATHODE RAYS—RÖNTGENOGRAMS OF MUMMY BONES.

BERLIN, June 10, 1905.

THE second Röntgen Congress was a great success. Men interested in this subject from nearly all of the countries of the scientific world were gathered together at Berlin, and although no new and striking discovery was announced, nevertheless the work that has been done by the Röntgen ray was thoroughly reviewed up through its most recent developments. The results of such a meeting of the best specialists in this line were most valuable. Although Röntgen himself was not there this fact must be accounted for by his modesty. The ovation that would have been tendered to a man who has made such brilliant progress within a few years in this work, he wished to avoid. In three days nearly ninety papers were read. They were so arranged that two days were devoted to the medical aspect of the question, while one day was given up to the technical side. More elaborate papers introduced a number of special ones according to the plan followed at the Surgeons' Congress.

v. Leyden and later Grunmach discussed the employment of the Röntgen ray in internal medicine. v. Leyden briefly spoke of the great advantages of the use of the Röntgen ray in the diagnosis of the diseases of the heart and large vessels, and of the lungs, and he treated in detail the disease of the vertebræ and of the spinal cord. By his researches he is now able to determine the early stages of spondylitis tuberculosa, spondylarthritis ossificans, as well as the presence of tumors. Fractures and dislocations of the vertebræ were easily seen by means of the Röntgenograms. Also in diseases of the spinal cord certain cases can be diagnosed very early. A fine paper, which met with great applause, was presented by Lenhartz of Hamburg, who described sixty-one cases of gangrene of the lungs that he had studied. These cases, which had been diagnosed by the Röntgen rays, had suffered insuperable difficulties when studied by other methods. He cured in this way 64 per cent., while previously 75 per cent. had died before the employment of the Röntgen ray. One especially interesting case was that which presented four foci. These were diagnosed and operated on one after the other. The case was illustrated by Röntgenograms.

Hennecart of Paris, Balsomoff of Sofia, and Köhler of Wiesbaden, discussed the question of tuberculosis of the lungs. The importance of being able to see the calcified bronchial glands was emphasized. Hennecart, especially, is so positive that a beginning tuberculosis can be detected by this method that he proposes that every pupil, every soldier, and every man who intends to take out a life insurance policy shall be so examined.

Branner, Holzknecht, and Weinberger, all from Vienna, agreed almost perfectly that this method gives a clear diagnosis in cases of diseases of the esophagus, stomach, and intestines, for by its aid the workings of the ingesta mixed with bismuth, can be oberved.

Hoffa of Berlin presented the chief paper dealing with diseases of the bones, and he gave a short sketch of the influence of the Röntgen ray in diseases of the bones and joints. He also recommended the use of the Röntgen ray in the treatment of these troubles by orthopedic apparatus. On this subject the paper read by Ludloff of Breslau was also of the greatest interest. He has found in his researches that in cases of pain in the lower part of the back due to traumatism, there is often a fracture of the fifth lumbar vertebra. Settegast of Berlin, from his work in relation to cases suffering from injuries to the ankles and feet, stated that the ligaments tear before the bones break. As to the question of foreign bodies, the greatest interest was centered upon their localization and upon kidney stones. Drüner of Frankfurt-am-Main demonstrated the position of certain foreign bodies, such as balls in the brain, by means of stereopticon Röntgenograms. Grashey of Munich showed an operating table so constructed that the operation could take place while the Röntgen ray was being used. By applying the compression diaphragm it now seems to be possible to find kidney stones in nearly all cases. Leonard of Philadelphia has been most successful in this line of work, failing to find the stones in only three cases out of three hundred and thirty-four.

Albers-Schönberg of Hamburg, and Sträter of Aachen, demonstrated by a number of Röntgenograms, the appearance of the normal kidney.

The question of the treatment of malignant tumors also came up for discussion, although there has been little advance in this work. Lassar of Berlin did not recommend the Röntgen ray for the treatment of the milder neoplasms, but he did advocate this method in the case of malignant tumors. The large tumors should be treated by other methods because the effect of the Röntgen ray does not extend to a great depth. Unger of Berlin demonstrated sections from a carcinoma of the mamma, which had been subjected to the Röntgen ray, in which the effect of the treatment did not extend deeper than 5 mm. below the surface. He added that up to the present time no absolute cure of cancer by the Röntgen rays has been observed. Schmidt of Berlin showed patients suffering from lupus, psoriasis, lichen ruber, and sycosis, who were cured by the Röntgen ray after all other methods of treatment had failed. Hennecart of Sedan was sure that the Röntgen ray produces sterility in male and female, and he declared that this method is already used by women for criminal purposes. For this reason he recommended the prohibition, by law, of this treatment.

In the technical section Max-Levy of Berlin recommended his protective covering, consisting of soft leather covered by a solution of metal salts, and he demonstrated a figure entirely covered by this tissue. Besides he has constructed a simple and excellent interrupter, which avoids the delay of the ordinary quicksilver interrupter. But the greatest interest centered in his new method of producing Röntgen rays by means of high tension alternating currents without an interrupter or condenser. All complicated apparatus is avoided by this new arrangement. The con-

sumption of the current is very small, and doubtless it will not be long before this method will come into common use. Wichmann of Hamburg demonstrated a new Röntgen tube, which permits only the rays used to pass out while it absorbs the other rays, which are injurious to both physician and patient. This tube also permits the treatment of deeper lying diseases, such as cancer of the uterus, fistulæ, and lupus of the interior of the nose. Robinsohn and Wendorff of Vienna have filled joints with oxygen and by this method have been able to see not only the bones, but also the ligaments, capsules, and cartilages. They demonstrated their beautiful results in a series of Röntgenograms, showing chronic joint diseases, such as tuberculosis, and joint deformities.

Strebel of Munich believes that he has been able to produce a more intense effect by the external cathode rays than by the simple Röntgen rays. These rays cause a very violent inflammation of the skin, and are useful for the treatment of lupus and cancer, which are affected in a far more efficient way by only one application than they are by other rays. Within two or three weeks the hairs fall out without any signs of a new growth. These rays leave very good scars, and thus the cosmetic effects of this treatment are happy. Finally, it is easy to direct them into the vagina and rectum for the treatment of new growths in those locations.

Albers-Schönberg, in experimenting with the bones of an Egyptian mummy 2,500 years old, found that the views of these bones were as satisfactory as those of fresh ones. It is impossible here to describe the Röntgen exhibition in its entirety. It was a most valuable conference, as had been anticipated. The most beautiful views were those of Richter of Munich, who showed pictures of the colon.

## "RESPONSIBILITY IN MENTAL DEFORMITY"—A CRITICISM.

To the Editor of the Medical Record:

Sir:—In an interesting and thought-stimulating article, entitled "Responsibility in Mental Deformity," in the Medical Record of May 27, 1905, Dr. James Weir, Jr., has well called attention to the wrong done certain unfortunates and the social state by classifying together the mentally deformed without disease and the insane whose insanity is due to disease. I have myself often wondered at the failure of the legal and clerical professions and public to recognize such distinction, but have thought it due chiefly to like ignorance displayed in medical writing.

The mind being dependent upon the brain for manifestation, it is evident that disease of the brain may interfere with normal mental activity, but it is not so generally recognized that among a given people mental obliquity in certain individuals, in contrast with the general mental qualities of that people, may be their normal state independent of inflammation, toxicity, syphilis, tumor, or other disease of the brain as an exciting cause. The lion kills, yet we do not attribute this animal's destructive type of mind to disease or even deformity of the brain. So individuals in society sometimes have normally (congenitally) so much of the lion type that they kill on slight provocation, while others whose whole previous behavior had been mild could commit murder only under the impulse of a diseased brain. Of course the brain of the murderous type may also become positively diseased, in which case, as in the lion, the murderous trait is apt to be further exaggerated.

But to our criticism. The author would seem, erroneously I think, to attribute cleptomania to a negative rather than a positive type of mind. To avoid possible misinterpretation I will quote: "Scientists tell us that there was a time in the history of man, when men held all things in common; 'mine and thine were unknown, and immediate possession was the only law. The dwelling, the boat, the spear, the cooking-pot, even the apron of leaves, and the wife, were communal; there was no mine and thine.' Owing to psychical deformity the cleptomaniac reverts to those ancient times; ethically he recognizes no difference between *meum* and *tuum*, and becomes, in this respect, the autotype of his savage ancestor. Modern law declares him insane; modern thought declares him psychically deformed."

Here the theory of evolution is raised, which in its broad meaning can readily be accepted, but we are led to infer that certain steps in that process had been so far accepted by scientists as to constitute science. It is asserted that in primitive man mine and thine were unknown, which may be interpreted as meaning that he had not the sense of property, that such instinct was of later development. Now, I will not pretend to say which of the existing animals were the ancestors of man, those which have or those which have not the sense of property, but it is certain that some presumably low in grade, as the squirrel, have the instinct to lay up, to hoard, strongly developed, while others which may be regarded as of higher grade have it not at all or only moderately developed, as the horse, dog, elephant. Neither am I in position to say that the marriage relation, the pairing instinct, is not of later evolution in man or his animal ancestors, but it is not, at any rate, always manifest in higher animals, as the horse, cow, dog, while it is strong in some lower in the scale, as the dove and fox. Even the races or individuals among men differ in degree in the strength of these two instincts, which possibly may be accounted for by difference of evolution through special environment since the primitive state of man, but which, for all scientists have demonstrated to the contrary as far as I know, may also have been due to some of our ancestors, coming up through those lower animals which possessed the instinct of property or marriage, while others sprang from animals deficient in one or both of these traits. It will not do to attribute the sense of property, the instinct to lay aside, to higher development of the moral sense, to honesty, for that would not account for its absence in the horse and its presence in the beaver. Among men some of the most moral, the most scrupulous in respecting the rights of others, are weak in getting and saving. Now it seems to me that cleptomania is a perverted or exaggerated action of the sense of property, a positive quality, not a negative quality which depends upon either moral turpitude or failure to distinguish between mine and thine. Indeed, some cleptomaniacs have had the sense of justice so strong, have recognized so clearly the rights of others to what belonged to them, that they have made prior arrangement to compensate for any theft which they might commit under the overpowering impulse.

If space permitted, the question might well be raised at this point whether the laws of modern society, which are based largely upon property rights, upon mine and thine in individual and family matters as distinguished from society interests, have not unduly influenced the views of anthropologists, especially in their conception of what may constitute mental qualities of higher or lower, earlier or later evolutionary development, and the part they are to take in the further history of evolution.

One more criticism. It may be inferred from the paper that the author is of opinion that all cases of mental deformity can be corrected if recognized and treated early. I am convinced this is not possible; that, like deformities of the body, some can be corrected possibly entirely or so far that they will not attract attention, but there are some which will persist through life, manifesting at times a "twist in the mind" to such degree as will render them liable to the restraint or punishment by society. But the recognition of the fact that there may be mental deformity independent of disease, that there may be strange types of character making the subject little more responsible than animals, will be better for such unfortunates and for society than to classify them among the insane whose insanity is due to disease.

## COCAINE IN OPIUM POISONING.

To the Editor of the Medical Record:

Sir:—Have we a safe and never failing remedy for poisoning by opium or its salts? I am sure we have. The history of one case will explain. Mr. A. B., 63 years old, married, became despondent over family troubles, and sought relief by the laudanum route. He took one ounce and was found in an outhouse about two hours later, with all symptoms of opium poisoning. The usual remedies were used—stomach pump, hypodermics of atropine, strychnine, and permanganate of potassium. The patient continued to sink. Six hours after taking the laudanum his life was despaired of by the attending physicians; the respirations were four to the minute; the pulse was barely perceptible at wrist, weak, and thready; the skin was cold and clammy; the eyes were not responsive to light or touch. This being a good case to test the efficacy of cocaine muriate, I gave at once 1-4 grain hypodermically, and repeated the dose every fifteen minutes. There was improvement from the first dose, and after the third dose consciousness returned, and the patient made a rapid recovery.

The point I wish to impress is this: When called to see a patient suffering from overdose of laudanum, opium, or morphine, the first thing to do is to give cocaine muriate in 1-4 grain doses. One should also use the stomach pump. Cocaine muriate and opium and its alkaloids are directly antagonistic in their action.

P. C. Gaston, M.D.

New Decatur, Ala.

**A Large Family in a Year.**—The Munich *Neueste Nachrichten* is authority for the statement that a certain Frau Hilgen of Trostberg, in Bavaria, has borne no less than six children in one year. She was delivered of triplets in January, 1904, and bore triplets again the following December.

# Progress of Medical Science.

*Boston Medical and Surgical Journal, June 29, 1905.*

**The Frequency, Prognosis and Treatment of Lobar Pneumonia in Infants and Children.**—In 217 personal cases of lobar pneumonia out of 839 cases of all forms of the disease, H. Koplik found the right upper lobe involved in 74, middle lobe in 8, lower lobe in 41, the left upper lobe in 35, and the lower lobe in 58. The prognosis depends on age, severity, kind of infection and complications, generally speaking cases below the tenth year offer the best prognosis. Out of the author's 82 cases extending over a period of four years, the majority of deaths occurred below the age of two and one half years (eight in number). The actual mortality of his cases was 9.7 per cent. The mortality is naturally greatest in winter. Complicating pericarditis is fatal, but above five years a pneumococcus pericarditis, a marked absence of leucocytosis foreshadows an unfavorable result. Otitis, pleurisy, and empyema do not materially influence the prognosis in infants and children if recognized early and properly treated. Treatment calls first of all for the management of the temperature if it is apparently doing harm. Here hydrotherapy is our sheet-anchor. Sponging and cold compresses are the preferable methods of application. The heart should be supported if necessary. Strychnine must be used with caution. The author has not seen much good result from the use of oxygen, but he insists on thorough ventilation—68° F. A sudden rise of temperature calls for examination of the ears. For cough and pain, codeia for older and paregoric younger children, meet all the indications. Calomel will relieve tympanites. Attacks of collapse are best combated by external heat to heart and extremities, with camphor and nitroglycerin internally.

**Acetonuria in Non-Diabetic Surgical Cases.**—Fourteen cases are reported by J. C. Hubbard. From these and cases reported by others, he offers the following conclusions: (1) Acetonuria is of more frequent occurrence than thought for. (2) Its presence without symptoms has no effect on operative treatment or prognosis. (3) Its presence with moderate symptoms is of only slight importance. (4) Its presence with severe symptoms is of the gravest prognostic value. Whether the severity of the symptoms on further study will be found to vary in direct proportion to the amount of acetone or diacetic acid present in the urine, Hubbard is not prepared to state. Several reports mention the use in such cases of bicarbonate of soda, in half dram doses every few hours.

*New York Medical Journal, July 1, 1905.*

**Varicella Gangrenosa.**—C. F. Kiefer reports a case occurring in a girl of sixteen months, who on the second day of the rash developed severe constitutional symptoms, and whose skin presented around several vesicles on the front of the chest and abdomen, the appearance as of a badly infected vaccination sore. Twenty-four hours later, the areas involved were covered with black, spacelated crusts. The condition became progressively worse for four days, the process becoming constantly deeper, until it seemed likely that in one place the abdominal wall would be perforated. The child did well, however, and recovered. The ulcer left at the above area did not heal entirely for four weeks. One application of bromine seemed to have a good effect. The smaller lesions left pitted scars not unlike those of smallpox. The author notes that the slough in the floor of the main ulcer closely resembled in color and appearance the exudate which covers surface wounds infected with the bacillus of diphtheria. To add to this, the child was in the same room with another child recently convalescent from diphtheria. Careful bacteriological examination failed, however, to show the Klebs-Loeffler bacillus. Direct examination of the exudate as well as inoculations, showed only the presence of the streptococcus pyogenes and the staphylococcus pyogenes aureus. No other organisms were isolated.

**The Etiology of Bradycardia.**—J. E. Greiwe reports one case with autopsy findings. The patient showed also evidences of the Stokes-Adams disease. The pulse rate ran from 30 to 38. The pathological findings were marked arteriosclerosis of the coronary arteries, aortic stenosis and insufficiency, pulmonary emphysema and sclerosis of kidneys, spleen, and liver. The heart muscle was not degenerated. The author says one should regard bradycardia not as a disease entirely, but rather as a symptom. He discusses the various theories of cardiac innervation, believing that the intracardiac ganglia have nothing to do with the cardiac evolution, but that they are to be looked upon as nervi nervorum. Clinically, bradycardia occurs most frequently with fatty degeneration of the heart. Next, with marked arteriosclerosis of the coronary arteries. Further, in other condition such as aortic, mitral, or pulmonary stenosis, acute cardiac dilatation and in rare cases of pericarditis, the ultimate conditions may be reduced to this—mechanical interference with the blood supply to the heart muscle, interference with the nutrition of the heart, interference with the metabolism of the heart muscle—hence a slower response, hence a prolongation of the refractory period. Interstitial myocarditis is evidently not an essential condition in the production of the slow pulse. It is one of the results of atheroma of the coronary arteries.

**How Far Shall We Go in Performing Multiple Operations at One Sitting?**—H. A. Royster discusses this question with special reference to gynecological work. He says that when multiple operations are demanded, it is better to do them all at one sitting. The patient is thus spared a second anesthesia and subsequent confinement, and chances for cure are equally good. There are limitations, however, to the number of operations to be done at one sitting, and, perhaps, in a given case there are contraindications which might make one or more of them inexpedient. The chief matter is the amount of time to be consumed. A careful estimate of this should be made beforehand, and, with an eye to the patient's powers of endurance, the definite methods outlined and arranged. In many cases of multiple lesions, the fundamental factor may be overlooked, and the patient, though operated on and recovering, be dismissed unrelieved. A practical lesson from this is the better taking of case-histories and closer physical examinations.

*Medical News, July 1, 1905.*

**Lavage of the Renal Pelves in the Treatment of Bright's Disease.**—The detailed histories of six cases are given by W. Ayres, who also describes the methods he prefers. His conclusions are thus stated: (1) Not enough importance has been given to the probability that a large percentage of cases of chronic nephritis, in whom no discoverable cause for the inflammation can be found, are really due to extension of inflammation from the renal pelves. (2) Lavage of the renal pelves is only applicable in selected cases of nephritis. (3) Lavage of the renal pelves will certainly cure a beginning nephritis that is due to extension of inflammation from the renal pelves. (4) Lavage of the renal pelves in subchronic and chronic parenchymatous nephritis will check the disease and markedly improve the general condition of the patient, in those cases that have not reached the stage known as cirrhotic kidney. (5) Lavage of the renal pelves for nephritis by one who is not properly trained in the technic, cannot possibly improve the condition of the kidney and may do harm.

**Fetal Manifestations of the Toxemia of Pregnancy.**—W. S. Stone records four personal cases. He says that the study of the lesions in the fetus must certainly establish their identity with those now recognized as associated with the effects of the eclamptic poison in the mother, as well as with those of other poisons. No uniform variations from the maternal lesions can be recognized in their distribution although possibly they may be considered in general to be less intense than those in the mother. Marked congestion and hemorrhages may be more uniformly present in the fetus, but no more than is seen in some individual examples in the mother. Cell destruction and necrosis is, however, not so uniformly present, although in certain instances the fetal liver cells have undergone marked changes. The prognosis for the fetus depends more on the duration than the intensity of the disease. The earlier in pregnancy, then, that disease begins, the less chance has the fetus for ultimate survival. In cases of short duration and severe intensity, although signs of asphyxia may be present, the child is frequently born alive. In cases of long duration, although comparatively mild for the mother, fetal death is more apt to occur, or, if born alive, the child is apt subsequently to develop eclampsia and die, presenting at the autopsy changes in the organs. As to the fetus itself being the etiological factor in the disease, it may be said that the following arguments have been advanced: (1) The more frequent occurrence of eclampsia in the later months of pregnancy; (2) its frequent occurrence in twin pregnancy, and (3) the cessation of the symptoms after the death or delivery of the fetus. Such fetal poisons even if small in amount, are harmful because they are delivered directly into the general circulation of the mother. If the latter eliminative functions are below par, trouble may result.

**What Advice Should Be Given to Women with Malpositions of the Uterus?**—C. G. Guild, Jr., says that such advice must depend on the class into which the individual case may fall. He divides all malpositions into (1) operative, (2) non-operative, and (3) questionable. The operative class may be further subdivided into those requiring immediate attention, and those in which it is safe to await for a reasonable time the convenience of the patient. Under the first subdivisions come those cases which may be classed as emergency ones, namely—inversion, incarceration, and irreducible prolapse of the gravid uterus, and adherent gravid retrodisplacements with symptoms of threatened

abortion. In the second subdivision are the complicated retrodisplacements, and hernia of the uterus either through the vagina or through the abdominal wall. In the non-operative class the author would include the uncomplicated retrodisplacements, and reducible hernia of the gravid uterus. The questionable class embraces the congenital type of cases, and retrodisplacements with symptoms relieved by reduction, but where the use of a proper pessary fails to accomplish an anatomical cure, or in young virgins where its use is unjustifiable. The congenital cases being errors in development are each a law unto themselves, and require a most thorough investigation. Where the retrodisplacement is the only abnormality present, the patient is often greatly benefited by an early operation, but where other marked evidences of maldevelopment exist the prognosis is unfavorable.

*American Medicine, July* 1, 1905.

**Rectal Alimentation.**—William Henry Porter reviews the literature on rectal alimentation and calls attention to the fact that owing to the limited amount of food that can be utilized in this manner, it is at best a very poor substitute for the natural method of feeding. It does in a measure relieve the pangs of thirst and hunger that of necessity follow the slow process of starvation which occurs when the stomach and small intestines are thrown out of commission. But so far as Dr. Porter's experience has gone, rectal alimentation has proved most unsatisfactory. He has tried all forms of substances, predigested and otherwise, for rectal alimentation, with but one result, namely, progressive starvation without the more intensely distressing symptoms.

**Two Cases of Korsakoff's Psychosis.**—Ross V. Patterson reports at length two cases which he regards as typical of this disease. He believes that only such cases as exhibit a pretty definite mental symptom-group due to some toxic cause and usually associated with multiple neuritis should be so regarded. Both cases reported were sudden in onset, of alcoholic origin and each exhibited the symptoms of ordinary severe multiple neuritis with marked weakness and inability to walk, disorientation as to time and place, marked fabrications, illusions of identity, hallucinations of sight and hearing, and defective memory with a certain peevishness and childishness of manner. After two months the mental symptoms in one case had improved sufficiently to show little more than feeble memory for recent events, and at the end of four months such improvement in the physical condition as gave promise of a more or less complete recovery from the multiple neuritis. The second patient died of cardiac exhaustion at the end of one month. Neuropathologic findings reported by D. J. McCarthy showed no gross change in the brain or spinal cord. Microscopical examination revealed marked degenerative changes in the anterior horn cells of the cord and throughout the peripheral nerves and muscles (Marchi method), pyknosis in some of the cells of the pyramidal layer taken from the rolandic area, diffuse moderate chromatolysis of the large Betz cells in the brain and a complete diffuse chromatolysis of the anterior horn cells in the cord (Nissl method). No changes were found in the subendymal tissues, neurolgia, blood-vessels, meninges, or by sheath stains in the spinal cord, medulla or brain.

**Some Phases of Tropical Malarial Disease.**—Thomas W. Jackson discusses some of the less common phases of malarial infection from the viewpoint of experience as an army surgeon in Cuba, the United States and the Philippine Islands, having studied 1900 cases in Cuba alone. His observations warrant the conclusions: Elevations of temperature and periodic paroxysms are not always present even in benign tertian infection; gastric and intestinal disturbances are sometimes the only expressions, even in an original case, and blood destruction may continue after objective symptoms disappear unless treatment be active and adequate.

**Surgical Aids in the Treatment of Paralyzed Muscles and Their Deformities.**—S. D. Hopkins asserts the treatment of paralyzed muscles and their deformities all depends upon the stage in which the case is observed. When mechanical means have failed to restore to usefulness, such surgical procedures as tendon transplantation or arthrodesis should be employed. The following precautions, however, should be observed in tendon transplantation: (1) Careful selection of cases. (2) Before muscle grafting is performed the electric reactions should be taken to determine the strength of the muscles to be transplanted. (3) The reinforcing tendon should be as nearly parallel as possible to the one to be reinforced and it should belong to the same muscle group, although this latter precaution is not absolutely necessary. (4) Overextension at the time of suture should be avoided, as subsequently the muscle will lose its contractile power. (5) The tension of the reinforcing muscle should be estimated by pulling upon it until it shows signs of complete resistancy. (6) Silk sutures should be used in the muscles quilted together firmly. (7) Strict asepsis should be observed during the operation.

*The Journal of the American Medical Association, July* 1, 1905.

**The Open Treatment of Burns.**—H. Sneve advocates the open method in the treatment of burns, that is, the disuse of occlusive dressings and reliance on strict cleanliness and perfect drainage for the healing of the injured surfaces. He remarks on the slight amount of pain in cases treated by the open method. When this is present, it is best relieved by morphine, but he advises giving as little of this as possible and none during shock. Another astonishing feature of the open treatment is the favorable character of the cicatrices which are smooth, flexible and skinlike. He says: First, treat the shock. Second control the pain as necessary and keep everything from contact with the burned areas. Third, keep the patient surgically clean. Ordinary surgical principles govern here as elsewhere; bichlorid of mercury, carbolic acid and other strong antiseptics are to be avoided when possible because they are such powerful cell poisons that toxic effects, both general and local, are to be feared; the delicate covering of granulations will not stand escharotic action without interfering with the production of smooth, flexible scars. Fourth, give frequent cold sponge baths to the sound skin with frictions, and keep the room temperature high. Fifth, cut away all blisters, cleanse with salt solution, dry thoroughly, and dust all second degree burns with stearate of zinc, carefully wiping away serous exudate until dry, brown, adherent crusts are formed. Sixth, leave third degree burns exposed without powder and keep surface clean until granulations are ready for skin grafting. Seventh, to maintain and to preserve function, body and limbs should be exercised as much as possible; the eschars of burns to fourth degree should be removed when nature so indicates and amputation should be performed when needed.

**Wandering or Aberrant Uterine Fibromyomata.**—Van Buren Knott gives the histories of two cases of detached or wandering tumors on which he operated, and a brief review of the literature of like cases which he has found rather scanty and unsatisfactory. The mode of their occurrence is explained by him substantially as follows; originating as sub-serous fibromyomata, they grow in the direction of least resistance and frequently become pedunculated. With the elongation and attenuation of the pedicle they acquire an increased range of motion and form "traumatic adhesions" to other abdominal viscera, acquiring a new source of nutrition, sufficient for their needs when that through their pedicle is cut off by rupture or atrophy. A tumor entirely loose in the abdomen, Knott thinks, could not long survive, and such as have been reported, he is inclined to believe, have been detached by the examinations to which the patients had been subjected. With their increased mobility, their interference with the functions of important organs to which they become attached, and their tendency to inflammation, they are more formidable than ordinary uterine fibromyomata. The treatment consists in removal when they are detected unless there are contraindications to operation.

**How to Use Antitoxin in Tetanus.**—J. Rogers says that it has been long known that prophylaxis is more effectual than treatment in tetanus. This means cleansing and thorough disinfection of the wound, and if the bacillus is found, immediate use of antitoxin continued daily for at least two weeks from the time of injury. As only that part of the toxin can be neutralized which is in the blood and tissues outside the nerves, the antitoxin should be injected directly into the veins and into the tissues surrounding the wound. Rogers advises the injection under proper precautions of 10 to 20 c.c. directly into the median basilic vein. Too little is more dangerous than too much. Next, the motor nerves supplying the infected region should be exposed as near the cord as possible, and each injected by a fine hypodermic syringe with five to twenty minims. He would pass a ligature around each nerve (except, perhaps, in case of the obturator) and leave it in place for the purpose of future injections as required. In addition to this blocking of the nerves he would go still further and block the spinal cord itself. If the injection is made into the cauda equina by lumbar puncture, assurance must be had by twitchings, etc., that one or more of the nerves in the cauda are injected. When symptoms are urgent he would inject the cord itself at the level of the sixth or seventh cervical vertebra, taking the risk of even a hemorrhage of the cord as a lesser evil than the spread of the tetanus infection. Local treatment of the wound is left to the last on account of the danger of multiple infection. It is imperative to destroy all the tetanus bacilli in or about the wound and the cleansing and disinfection must be most thorough. In extensive laceration or contused wounds this is impossible, and the only logical recourse is amputation of the member as near to the body as possible. The whole process, including the anesthesia, blocking of the nerves, etc., should be repeated every day

until the symptoms subside. The patient's strength should be kept up by the usual remedies of quiet, nutrition and antispasmodics, of which the best seem to be chloral, morphine and the bromides.

**Appendicitis in Trained Nurses.**—J. N. Hall remarks on the frequent occurrence of appendicitis in the trained nurses at the Denver City and County Hospital where he is a member of the medical staff. Excluding mild non-operative cases, he has records of 18 patients operated on among the pupils of five Denver training schools, the total number of nurses during the time under consideration being 296. Thus 6.08 per cent. were operated on, while a considerable additional number had mild attacks of the disease. Thirteen were operated on at the beginning of an attack and five were interval operations; the average age of the patients was 23½ years, the average duration of training at the time of operation was about 14 months. Every patient recovered with a practically perfect result. While he can only theorize as to the causes of this frequency, he suggests the unaccustomed requirements in many cases of standing and walking, constipation and trauma from action of the psoas muscle in working in the stooping position so often necessitated in the nurse's occupation, as worthy of consideration. The greatest single factor, however, he thinks is, the prompt recogniton of the condition, leading to an early and successful operation. If all cases could be managed as well, he believes the mortality of appendicitis could be practically wiped out.

**Relieving Uremic Hemiplegia by Lowering Intracranial Pressure.**—Robert N. Willson reviews his later experience in relieving intracranial pressure by lumbar puncture and drainage. He reports and analyzes briefly a number of cases thus treated, describes the other treatment employed and discusses the special points involved. He believes the following conclusions, here given in substance, to be warranted by the study of these cases: (1) Various toxins are influential in producing uremic symptoms; the most important of these is probably one originating in an abnormal digestive tract and resembling adrenalin in its physiological action. (2) Resulting from or coinciding with, toxic action, intracranial tension due to accumulated cerebrospinal fluid may and usually does cause most of the classic uremic symptoms and is often the dominant influence. (3) Spinal drainage only, and often does, relieve the symptoms of uremia. (4) Occasionally, however, when intracranial pressure has been relieved the toxin alone may cause the uremic symptoms. (5) Uremic manifestations (other than coma) due to intracranial pressure may be general or localized, including unilateral convulsions, monoplegia, hemiplegia, etc. The toxic influence independent of pressure causes only general manifestations, usually of an irritative and seldom or never of a paralytic nature. (6) Uremic hemiplegia and other uremic paralyses are usually due to direct pressure on or edematous infiltration of cerebral motor centers, and are then relieved by withdrawal of cerebrospinal fluid. (7) The frequent absence of general edema with an excess of intracranial fluid is suggestive. (8) Lumbar drainage should be used as a routine measure together with the other known means of reducing hypertension. (9) The ultimate cause of arterial hypertension of uremia is yet unknown. It seems not impossible that the fluid pressure is due to toxic inflammatory exudate producing intracranial hypertension and favoring a similar condition throughout the system; and that the symptom-complex of uremia is due to such a sequence of causes. Probably uremia cannot occur in the presence of low intravascular and intracerebral tension. (10) It would seem from experimental evidence that the toxic principle of uremia is not found in the cerebrospinal fluid. The experiments of Hughes and Carter in 1803 seemed to show that it may possibly be found in small quantities in the normal blood serum. (11) While lumbar puncture is not infallible or free from slight risk, it should be employed early and repeatedly in uremia if necessary to relieve hypertension; it may be life-saving and will often dissipate uremia for the time being. (12) Transfusion of salt solution is harmful in uremia by increasing hypertension and favoring some of the conditions of uremic seizure.

*The Lancet, June 24, 1905.*

**A Case of Aneurysm Simulating Dyspepsia.**—R. H. Corduer reports the case of a man of thirty-five years, complaining of indigestion. Some pulsation was visible in the epigastric notch which presented a sense of resistance, but no definite tumor. A faint blowing murmur was localized over a portion of the area. An *x*-ray test gave no shadow. The patient died suddenly three weeks after he entered the hospital and the autopsy revealed an aneurysm about the size of a small pear, involving the whole of the celiac axis artery and anterior aortic wall. It had ruptured into the peritoneal cavity. The splenic artery came directly out of the wall of the sac, which was nearly filled with an antimortem clot.

**Ringworm of the Scalp Treated by X-Rays.**—H. G. Adamson commends the use of the *x*-ray. He finds that if the proper precautions are taken, viz., (1) that the length of exposure is not allowed to exceed the limit set by the right use of the pastille; (2) that no area or part of any surface is exposed more than once; and (3) that the part exposed is kept at the proper fixed distance from the anticathode of the tube—there is no danger of permanent baldness or injury to the tissues. At the same time care must be taken that the exposure is sufficiently long or the fall of hair will not be complete and many diseased stumps will be left behind, requiring needling or other treatment afterwards. When a part only of the scalp is being treated, the remainder must be anointed frequently with a mild parasiticide or the falling hairs from the diseased patch will spread the disease elsewhere; this is explained by the fact that cultures of the fungus can be obtained from the depilated hairs showing that it has not been killed by the action of the rays. The "pastille" referred to by the author is a device, made from the paper of the ordinary fluorescent screen, for measuring the proper dosage of the rays. Its mode of use is described in full by the author.

**A Case of Polyarticular "Quiet Effusion."**—The patient of T. B. Jobson was a woman of twenty-four years, who for a year, had had symmetrical effusions of the knee, wrist, and first pharyngeal joint of the hand. There was a distinct family history of rheumatism. The attacks had begun when she was nine years old, and the various joints had been involved at different times. The attacks invariably came on in winter, but regularly subsided with the recurrence of warm weather. The patient was anemic and suffered from indigestion. The heart was sound, but she had had considererable amenorrhea, though its occurrence did not seem to bear any relation to the joint trouble. Regulation of these various functional abnormalities did not prevent the recurrence of the effusions. The author suggests that the condition may be either a neurosis or some form of arthritis, inclining to the former view. No form of treatment seemed to produce any lasting benefit.

*British Medical Journal, June 24, 1905.*

**The Induction of Labor: A Comparison of Some of the Methods, with Notes of Five Recent Cases.**—J. Spencer Sheill cites a short series of cases in which the methods used to stimulate uterine contractions were bougies, drugs—quinine—separation of membranes from the lower uterine segment, plugging, and instrumental dilatation. The writer calls attention to the grave risks of laceration always present when artificial dilatation is practised, more especially when carried to the full degree. In three of his cases when the circular fibers were artificially dilated the body of the uterus vigorously contracted by virtue of the intimate nerve connection between the segments. The writer advocates the use of the branched dilator, and prefers it to the inelastic bag of Champetier de Ribes. He considers it safer not to use it unless the cervix is taken up largely, if not entirely. He states that, working upon past experience, when a case comes under his care which for one reason or another requires induction of labor and great haste is not essential for the safety of the patient, if the os be small, he dilates up to about No. 16 or 18 Kelly's dilators. Three of the largest bougies capable of passing through the os at the same time are inserted into the uterus, and the vagina is tightly plugged with sterilized gauze. If this has not the desired effect in twenty-four hours, he advises a repetition of the treatment. As soon as the cervix is partly taken up, if the uterine contractions are not strong, he uses the Frommer dilator to stimulate them. Should the membranes be accidently ruptured during the use of the dilator, he says he would be tempted to use the hydrostatic dilators, but not until then.

**The Spread of Cancer by the Thoracic Duct.**—Nathan Raw has often observed that malignant disease of the glands of the neck occurs far more often on the left side than on the right. He has also often seen cases of apparently primary cancer in these glands without any evident focus of infection. He reports the case of a man, forty-six years of age, who began to complain of want of appetite, constipation, increase of weakness, and a gradual and steady loss of flesh. Two months before admission to the hospital there developed a hard, inflamed swelling on the left side of the neck; loss of vision in the left eye was noted at the same time. The patient had no active gastric symptoms. Over the splenic area there was some pain and a sense of resistance. Necropsy revealed a cancerous pancreas. The left side of the neck, including all the triangles, was involved in an irregular cancerous growth, evidently originating in the deep part of the subclavian region. Near its termination, the thoracic duct was found to be cancerous. This new growth was a typical glandular carcinoma. It is possible, so the writer states, that a more minute search in all cases of abdominal cancer would point to the more

common spread to other viscera and lymphatic glands by means of the thoracic duct.

**Dilatation of the Gall Bladder Simulating Ovarian Cyst.**—J. Basil Hall reports this case. The patient was seized with acute abdominal pain, vomiting and fever. A swelling in the abdomen which she had noticed for several months had become acutely tender. It extended upwards on the right side from the pelvic brim; it was oviform in shape and apparently cystic. Below the umbilicus the swelling extended to the left of the middle line, forming a second tumor like a small cocoanut. Ovarian cyst with twisted pedicle was the diagnosis, and celiotomy was performed. The left-sided tumor was found to be a cystic left ovary; it was almost gangrenous from twisting of the pedicle. The large mass of the tumor on the right side was a dilated gall bladder reaching to the pelvic brim. Over a pint of purulent fluid was evacuated from it, and a large impacted stone was removed. Recovery was uninterrupted. The symptoms of twisted pedicle had been attributed to the wrong tumor.

**Suspended Respiration Under Chloroform.**—H. Norman Barnett describes the following case: The patient at operation took chloroform badly at first, but later her condition was good, although the face was slightly cyanosed. About twenty minutes after the operation began, after the cervical glands had been removed, the pupils became widely dilated. A few minutes later without further warning respiration ceased. Artificial respiration was begun, nitrate of amyl capsules were used, and a hypodermic of strychnine was given. The pulse slightly improved, but respiration remained suspended. A second hypodermic of strychnine was given, but the radial pulse ceased to be perceptible and the heart could not be heard. Three bags of oxygen were given, artificial respiration being kept up, and the radial pulse again became perceptible and feeble breathing began. In about fifteen minutes the patient had entirely recovered. The writer insists that the anesthetic should be at once suspended if the pupils become widely dilated. He also calls attention to the importance of oxygen in restoring respiration.

*Berliner klinische Wochenschrift, June* 12, 1905.

**The Pathological Anatomy and Path of Infection of Cerebrospinal Meningitis.**—Westenhoeffer, who was sent to Silesia to study the prevailing epidemic of cerebrospinal meningitis, comes to the following conclusions. The portal of entry of the infective agent is the posterior nares, particularly the pharyngeal tonsil. The inflammation of the meninges is always a basilar one in the beginning, and starts in the neighborhood of the hypophysis. It arises by way of the lymphatics. The affection of the meninges as evidence of the involvement of the cranial cavity, is analogous to the inflammation of the mucosa of the accessory cavities of the nasopharynx. The meningitis never, or only very rarely, arises through extension of inflammation from the ethnoidal cells. The disease is essentially one of childhood and all the patients present distinct evidence of the co-called lymphatic diathesis. The disease is transmitted by inhalation, and its prophylaxis is largely to be founded on household hygiene. The meningococcus Weichselbaum-Jaeger is found in most cases, but it has not yet been clearly shown that this is the only exciting agent of the disease. The fact that other cocci are sometimes found either alone or mixed with the meningococcus, does not preclude the possibility that all these bacteria play only a secondary rôle, and that the real causative organism is still unknown.

**Observations on Recent Cases of Cerebrospinal Meningitis.**—Grawitz takes the ground that cases of cerebrospinal meningitis should not be called epidemic cerebrospinal meningitis unless they really give rise to an epidemic, and he proposes as a preferable name for the ordinary sporadic cases the term infectious or contagious meningitis. Of seventeen cases recently sent to the Charlottenburg hospital with the diagnosis of meningitis, on careful study three proved to be only gastrointestinal conditions with cerebral symptoms and four were secondary to various other conditions. Of the ten remaining, only three were of the true sporadic variety, the other seven being tuberculous, and no other cases of the sporadic form were reported in spite of the fact that the patients came from very crowded quarters. Grawitz, therefore, considers it a misnomer to call such isolated cases epidemic, and he emphasizes the necessity for sufficient delay before making a diagnosis.

*Münchener medizinische Wochenschrift, June* 13, 1905.

**The Occurrence of the Spirochæte Pallida in Syphilis.**—Fraenkel, while approaching the subject cautiously, concludes from his own observations and those of others that the spirocheta discovered and first described by Schaudinn and Hoffman is the causative agent of syphilis. His own material comprised freshly excised primary lesions, as well as the juice from swollen glands, condylomata, etc. In six cases of syphilis the spirocheta was found, while in one case of pointed condylomata of nonsyphilitic origin it was absent. The search for the organisms is a difficult and protracted one, which requires an oil immersion lens with the No. 8 eye piece, and even the trained eye cannot continue at it for longer than three to four hours a day. The method used was the one originally recommended, and consists in fixation of the smears for ten minutes, alcohol and staining for sixteen to eighteen hours in Giemsa's solution. The length of the organisms is very variable, and they range from those with four to six turns to others with twelve to fourteen; eight to ten being the commonest number. Their distribution is very irregular and sometimes after hours of fruitless search numerous individuals will suddenly be found in several fields. Usually about a dozen are found in a single preparation, but sometimes smears treated in exactly the same way as their barren companions, will reveal five or six in every field. The organisms were never found in preparations obtained from other than syphilitic lesions.

**The Physiological Significance of the Omentum.**—Heusner reviews the evidence cited by those who ascribe to the omentum a purely protective function, and comes to the conclusion that this view is untenable chiefly because there is no organ in the body designed only for use under pathological conditions. By studying the development of the omentum he endeavors to show that it principally serves in a mechanical way, and that it furnishes a supporting apparatus which provides the stomach with its posterior mesenteric layer, and supplies the lower abdominal organs with a substitute for the lost anterior intestinal mesentery. He then goes on to study the conditions existing in other mammals, and points out that the greatest use is made of omental fixations in those animals that make the most violent movements and possess the heaviest viscera. Phylogenetically, therefore, the omentum is a suspensory organ used for the purposes of fixation, as is clear from its relation to the transverse colon, but the status of the free dependent portion is less evident. Man, however, occupies an intermediate position between the carnivora and herbivora, and it is not strange that his omentum should present reminiscences of his descent from both groups. The fixation of the stomach to the stomach recalls the structure of the ruminants and the animals that walk upright, while the free omental apron is a vestige of the huge omental layer of the animals of prey, that is a rudiment like the vermiform appendix, recalling earlier stages of development.

**Castration for Carcinoma of the Breast.**—Michels cites several cases from the literature in which very good results were obtained by oophorectomy in carcinoma of the breast, and describes three cases of his own in which the measure seemed to have exerted a distinctly beneficial effect. His opinion is that oophorectomy is in many cases of inoperable or recurring cancer of the breast, an excellent palliative measure, which without involving serious danger, relieves suffering and prolongs life. It is at present impossible to indicate exactly what are the indications for the operation, but the most favorable cases are those of patients between forty and forty-seven years old. Earlier than this and after the age of fifty the prospects are not nearly so good, and the operation should not be done after the menopause or the development of internal metastases. A cure is not to be expected from oophorectomy, and this should be explained to the patient's friends. No satisfactory explanation of the manner of action of the procedure has yet been offered.

*Deutsche medizinische Wochenschrift, June* 15, 1905.

**The Effect of Alcohol on the Human Circulation.**—Kochmann says that the literature of this subject is full of contradictions, and that different observers have reached widely differing conclusions. Some consider the action of alcohol on the heart and circulation a favorable one, others, while not denying it all virtue, believe that it could be dispensed with as a medicinal agent, while a third group condemn it utterly, and would banish it from the materia medica. Kochmann's observations were made by means of the Gärtner and Riva Rocci instruments, and by the sphygmograph, after the administration of small quantities either of diluted pure alcohol or of eighteen per cent. port wine. He concludes that given in suitable doses, alcohol produces a rise in blood pressure which is due to a vasoconstriction in the splanchnic area, in spite of simultaneous peripheral dilatation. Animal experiments showed that the heart muscle was better supplied with blood and therefore stimulated to increased activity, but to what extent these results may be transferred to pathological states is undetermined. It is certain, however, that alcohol is entitled to respect as a therapeutic agent, although whether it might be desirable from social considerations to replace it by other drugs, is a question still to be decided.

**Traumatic Diseases of the Upper Esophagus and Their Treatment.**—Glücksmann considers the lodgement of foreign bodies in the esophagus under this title because he says that both physician and patient often forget the possibilities following the extraction of foreign bodies from the eso-

phagus and consider that the matter is terminated when the object has been removed. Infection with rise of temperature mediastinitis, pyemia, etc., not infrequently follow the accident, but are then by the patient's friends nearly always ascribed to the instrumental manipulations of the physician instead of to their true cause, the injuries to the mucous membrane inflicted by the foreign substance itself. The medical attendant should, therefore, always warn the family of this possibility before undertaking any manipulation, in order to save himself from disagreeable consequences. In attempting to locate the foreign body the author says that the patient's sensations are often of value, for if on being asked to point out its position he puts the finger into the mouth, it will always be found above the pharyngeal constrictors, while if he indicates some spot on the outside of the neck, the object, or at least the injury caused by it, will be found lower down. Röntgen ray examination is always of great value, as even if it does not clear up the position of the object swallowed, it reveals any possible thoracic complication such as aneurysm which would forbid esophageal instrumentation. For the actual removal the author counsels the use of as few instruments as possible in order to avoid all needless traumatism. He has perfected for the purpose an esophagoscope with forceps combined, and provided with a distensible water cushion, so that after the object has been found and seized, the walls of the esophagus may be separated ahead of it during withdrawal so as to avoid all scratching of the mucous membrane.

*French and Italian Journals.*

**Chronic Appendicitis.**—Comby, after referring to the communication of Siredey on this subject, reports a most interesting observation. His patient was a young man twenty-five years old, who had been perfectly well up to the age of twenty-one. At this time he began to lose weight and spirits. He suffered from symptoms of dyspepsia which pointed to some disturbance of the stomach. Even his disposition changed and he was considered a neurasthenic. One time during an attack of indigestion, Comby examined him and found a painful spot over McBurney's point. The crisis subsided but a history of analagous paroxysmal phenomena was obtained. Comby concluded that the case was one of chronic appendicitis and the patient underwent an operation. The appendix was very much altered. The patient has gradually regained his health.—*Gazette des Hôpitaux Civils et Militaires, May* 30, 1905.

**Injections of Isotonic Sea Water in Eighteen Cases of Tuberculosis.**—Chauffard has reported the results obtained by Robert-Simon and René Quinton in the treatment of tuberculosis by subcutaneous injections of isotonic sea water. These investigators have treated by this method eighteen cases of tuberculosis, three of which were unsuccessful. One of these was the pulmonary type, the other two being ganglionic. Rapid improvement which took place was first noted in the general condition. The injection of sea water stimulated the appetite, cured insomnia, imparted strength, and diminished cough, expectoration, and night sweats. Physical signs also underwent a great improvement. Not only was there in some cases a partial return to normal of respiratory rhythm, but in others it was complete. In one pulmonary cases of the third degree, there was an absolute drying up of a cavity. This condition was reached in a relative degree in two other cases, with suppression in one of daily bloody sputa. This condition has now lasted for two months. Finally, weight has increased in a regular manner, often at a most astonishing rate. For these fifteen patients whose condition has been improved the mean duration of the treatment has been sixty days. The treatment has consisted of injections every three or four days of from 50 to 300 c.c. of isotonic sea water sterilized by cold. —*Le Bulletin Médical,* June 7, 1905.

**The Treatment of Syphilitic Coryza of the New-Born.**—Laurens believes that not even the common ureteral syringe should be used in these cases, nor should any antiseptic solution be employed on account of the danger of intoxication. Any injection into the nasal fossæ is dangerous in the new-born, because of the risk of the purulent mucus penetrating the eustachian tube; and in addition, the dropping of liquid into the larynx can cause a glottic spasm with all of its consequences. It is not well to use cocaine. Laurens treats these cases by hydrogen dioxide which he introduces into the nose by a drop bottle, three or four times a day. He uses four or five drops of the dioxide to about four times its volume of water. This method is excellent for breaking up the crusts and for bringing about antisepsis of the nasal fossæ. These instillations of the dioxide ought to alternate with others in which oil or sterilized vaseline is used. He warns against the introduction of probes into the nose of the new-born for cleansing purposes, on account of the great difficulty of keeping the child's head quiet. In order to lessen the nasal obstruction and to facilitate nursing, it is well five minutes before feeding, to instil into each fossa from three to five drops of a ten thousandth solution of adrenalin hydrochlorate. This brings about a vasoconstriction of the mucosa, and will establish for the time respiratory permeability. If this method fails, the child should be fed by a spoon, or if it is necessary, by an esophageal catheter.—*Revue Française de Médecine et de Chirurgie,* June 5, 1905.

**Uterine Metastasis in a Case of Cancer of the Stomach Which Appeared in the Course of Pregnancy Necessitating the Cesarean Operation.**—Couvelaire relates this case. The patient, a woman thirty-five years of age, pregnant two months and a half, presented herself at the clinic on account of uncontrollable vomiting. For several months she had suffered from dyspeptic troubles, which had increased with pregnancy. A diagnosis of gastric neoplasm was made. Treatment met with improvement for a time, but at the seventh month the patient's condition was becoming rapidly worse. Extreme ascites developed. The lower extremities were markedly edematous. Labor had not begun three hundred days after the end of the last menstruation. On the next day, Pinard in his examination, found to his surprise that the vagina which had up to that time been elastic, was transformed into a rigid canal, and the cervix was an indurated ring. Cesarean section was practised. Although a living infant was extracted, it died at once. The neoplastic infiltration of the lower segment had extended high enough to indicate Porro's operation. In spite of intervention, however, the patient died two months afterwards. Autopsy revealed the presence of a neoplasm of the stomach, of the large intestine, and of the uterus. The gastric cancer had not ulcerated. All of these malignant growths were found to be of the same histological type.—*La Tribune Médicale,* June 3, 1905.

**Antimalarial Prophylaxis in the Forts About Rome.**—G. B. Mariotti-Bianchi details the results of observations made on the regiments which are quartered for a month at a time in the forts of the malarial Roman Campagna. These forts were divided into three groups, and in each group a different method of prophylaxis was used, and the results observed. In the first group mechanical prophylaxis was used, the rooms being all screened at both windows and doors, and the men, when out of doors, using gloves and helmets provided with veils that covered the face and neck entirely. In the second group the men received small doses of quinine daily; the third group received large doses of quinine once a week. Each experiment lasted one month. Where the mechanical protection was used there are few inhabitants, and at times the epidemic has been very severe. In 1900 it was very severe; 1901 it was mild, in 1902 there was almost none. In group two almost all the inhabitants had malaria in 1901; in 1902 there were many returns from 1901. In group three the epidemic was diffused in 1901, and even more so in 1902. Mechanical protection succeeds well where the number of persons is small, but with great numbers it becomes ineffective and burdensome. The administration of small doses of quinine has no inconveniences and results well. Where large doses were taken once a week the inconveniences were marked and the protection was no better. The author believes that large doses of a gram a week are insufficient; at least two grams per week should be taken. The administration of small daily doses acts better and in quite sufficient protection.—*Giornale Medico del Regio Esercito,* May 31, 1905.

**Direct Inguinal Hernia in Women.**—Marie Donati believes that the smaller number of hernia of the direct inguinal type that we find in women, is due to the different formation of the inguinal canal in the two sexes, and to establish this conclusion he has dissected 52 cadavers of both sexes, 31 women, 21 men, and has found marked differences in the canals in the two sexes. The aponeurosis of the insertion of the great oblique muscle has linear interstices, which are much larger in the male than in the female. The pillars of the internal oblique are stronger in front of the canal in women. The arciform fibers (intercrural) are in the women often mingled with cross fibers which strengthen the ring, which are absent in men. The orifice of the external inguinal ring is generally smaller in females than in males. The ring is generally situated higher and a little more external in men than in women, contrary to what has been supposed to be the case. The aponeurosis of the large oblique, which forms the anterior wall of the canal, is much stronger in the female sex than in the male. The lower margin of the ring in women is more horizontal, that in the male more oblique. Hence this point, which is often weak in the male, is in the female most resistant.—*Archivio per le Scienze Mediche,* N. 3, 1905.

**Medically Trained Legislators.**—Dr. H. W. Wiley says that there were but three physicians in the Fifty-seventh Congress, as contrasted with 319 lawyers. He thinks it strange that this great law-making body of the country should contain so few medical men. Medicine is a jealous mistress, and demands undivided devotion from her followers.

# Society Reports.

## MEDICAL SOCIETY OF NEW JERSEY.

*One Hundred and Thirty-ninth Annual Meeting, Held at West End, Long Branch, June 20, 21, and 22, 1905.*

(Special Report to the MEDICAL RECORD.)

THE PRESIDENT, DR. WALTER B. JOHNSON OF PATERSON, IN THE CHAIR.

**Reports of Committees.**—The first morning session was devoted to hearing the reports of the various committees. Of particular interest was the report of the Committee on Publication, showing that the first year in the history of the New Jersey State Medical Journal had been one of success. The afternoon session was opened with prayer by the Rev. Elliott White. The Mayor of Long Branch, the Hon. C. A. Francis, made the address of welcome, which was responded to by the President.

**Therapeutic Agents of Animal Origin.**—Dr. GEORGE E. READING of Woodbury read this paper and said that the animal economy contained agents capable of influencing the course of disease, and this was an idea of very ancient origin. It could be traced back through Grecian literature into Persia, where it was lost in the mists of antiquity. The object of his paper was to call attention to those substances existing in the normal animal organism which were capable of being used with good results in the battle against disease. Pepsin was probably the first to receive the attention of the profession, and still commanded an important position, but one not so important as formerly in the treatment of diseases of the stomach. Of the remedies obtained from the glands themselves adrenalin stood at the head. After referring to its use in the treatment of a large fatty tumor and in carcinoma, he took up briefly a consideration of the treatment of myxedema and cretinism by the administration of thyroid gland. He said that if the members of the Society could be persuaded to lend their assistance in determining, by clinical tests, the therapeutic value of this class of remedies, which seemed to offer such a wide field of application, the object of the paper would be attained.

Dr. L. M. HALSEY of Williamstown thought that the profession should feel proud of the additions made to therapeutics in the last fifteen years by the use of the animal products, and believed the future was rosy with hope that many more effective aids in the cure and alleviation of disease would be added as a result of investigations already in progress.

Dr. WM. GRAY SCHAUFFLER of Lakewood, Dr. TREGANOWAN of South Amboy, and Dr. CUTHBERT WIGG of Boonton also discussed this paper.

**The Proof of the Existence of Amblyopia Ex Anopsia in Strabismus.**—Dr. WALTER B. JOHNSON delivered this address. He said it had been the result of unusual experiences which had led up to the circumstances which permitted the offering of what appeared to be positive proof of the existence of amblyopia ex anopsia, which was the impairment of vision occurring in consequence of the disuse of the eye which had been excluded from the visual act for a considerable period of time, by absence of binocular fixation. In convergent strabismus, which was the symptom resulting from this condition, there was, if the squint was not of the alternating variety, invariably a monocular diminution of vision which was more or less marked. Hypermetropia was, it was believed, the etiological factor in the production of this condition. After relating the histories of three cases, he concluded that the existence of amblyopia ex anopsia as a condition was positively proven by the almost invariable return of absolutely normal vision in the amblyotic eyes; that the control of the vision of the amblyotic eyes by the cerebral centers was positively indicated through the confusion of images caused by the mental impression that the normally seeing eye was about to engage in the visual act when the injured eye was not covered; that, as instanced in one of the cases, the vision in the left eye would become normal providing the stimulus of exclusive sight perception should be permanently established in that eye by loss of vision in the right eye, or in case an operation should be performed which resulted in the attainment of perfect binocular fixation; that the amblyopia of squinting eyes was a consequence and not a cause of squint; that it was not at all probable that congenital amblyopia, the result of cerebral lesion or diseased conditions, would completely disappear and the eyes regain their normal vision under any imaginable circumstances; that changes in the muscular balance of the eyes affected by congenital amblyopia, the result of cerebral lesion or discoverable disease, were more likely to be in divergence than convergence; that after the loss of the seeing eye, in this condition, the hypersensitive retinal area developed as a result of the changed position of the point of convergence of the visual lines, lost its increased visual power and the macular region resumed its functions as the visual center; that hypermetropia was the etiological factor in the production of amblyopia ex anopsia; and that it was most probable that squint and subsequent amblyopia was the direct result of hypermetropia in which there was primarily a difference in the degree of the refractive error and in the vision of the eyes; that in the cases reported the amblyopia was not due to structural changes either in the eyeball or nerve centers, but to continued suppression of the visual image induced by convergence of the visual lines superinduced by an hypermetropia.

**The Trained Nurse and the Doctor—Their Mutual Relations and Responsibilities.**—Dr. EDWARD J. ILL of Newark read this paper.

**Surgical Diagnosis.**—Dr. FRANK D. GRAY of Jersey City delivered this oration. After making a brief retrospect, he said that in seeking the cause for faulty surgical diagnosis he would consider (1) superficial acquaintance with anatomy, physiology, and pathology; (2) carelessness in taking and recording history and symptomatology; (3) neglect of the assistance of modern aids in diagnosis; (4) undue haste in dealing with obscure or chronic cases, indecision and delay in the presence of acute or traumatic conditions; (5) not infrequent neglect by the internist to recognize promptly or even suspect the possible surgical nature of supposed non-surgical conditions. As a rule no operation was justified until one had, with approximate certainty, determined that a surgical lesion or condition existed, and, in addition, where and what it was. There was no royal road to diagnostic success. Only by acquiring the elemental knowledge, educating the eye to observe, and the ear to hear comprehensively and shrewdly, and seeking to interpret properly the data obtained through well developed reason and wide experience, was the true diagnostic acumen attained.

**Difficulties in the Diagnosis of Abdominal Conditions.**—Dr. RICHARD P. FRANCIS of Montclair presented this paper, which was read by Dr. RICHARD C. NEWTON. He detailed the histories of two cases, in one of which there were supposed to be intestinal adhesions when there were none, and, in the second, adhesions were not supposed to be present but were found. Certain detailed methods to be employed in making an examination of the abdomen were presented, and the following conclusions drawn: The diagnosis of abdominal conditions depended very largely on the skill and training of the examiner as well as on the physical and other characteristics of the patient; the examination should be systematic and thorough; inspection, palpation and percussion, with the patient both supine and erect, were the best means for diagnosis; bimanual examination and particularly examination of the pelvis should never be omitted; a general anesthetic was sometimes, though rarely, needed; it was very important that not only the entire abdomen but the entire body should be examined so that all the conditions of every organ could be noted; exploratory laparotomy was often warranted in doubtful cases, and the decision when to employ it was one of the nicest points in modern surgery.

Dr. JOHN A. WYETH of New York directed his discussion

of the difficulties in the diagnosis of abdominal conditions to the laboratory side. Scarcely a week went by but what he was called to the laboratory for help. Especially in lesions located in the right iliac fossa where the physical signs and febrile movement might suggest either beginning typhoid, intestinal toxemia, or a pyogenic sepsis, an early diagnosis could be made in no other way than by the laboratory. Its value was accentuated in the knowledge that the safety of the patient hung upon even a few hours time. The pulse and temperature of a commencing typhoid might well be mistaken for those of an appendicitis, pain and muscular resistance over the right iliac and the right abdominal region in many instances were practically alike, the nausea, vomiting, and general sense of uneasiness pointed neither directly to the one nor the other; but in a crucial test by Widal's reaction with the blood count pointing to the presence or absence of a leucocytosis the question was quickly settled. He had seen all the symptoms of appendicitis in which the blood count contraindicated a pyogenic sepsis and in which Widal's reaction told the story of typhoid. He also had dealt with cases which would have been most perplexing in which all the signs of typhoid prevailed at a period when it was too early to recognize this disease by Widal's test and a leucocytosis of 15,000 to 20,000, proved at the earliest possible moment the case to be one for immediate operation. Bacteriological research had rid the puerperal state of much of the anxiety and dread which formerly attended this ordeal, not only in preventing sepsis, but in recognizing the infections already established in time to prevent a general peritonitis or septicemia. One of the most important fields for laboratory diagnosis was in certain obscure lesions of the stomach, as well as in arriving at the exact condition of the digestive functions of this organ. The presence of lactic acid in the stomach contents had a diagnostic value, since it took place in comparatively rare conditions, and since those conditions were seldom fulfilled except when carcinoma was present. He said that Boas had gone so far as to insist that the persistent presence of lactic acid in noteworthy quantities, chemically free from hydrochloric acid, during the digestion of a saucer of oatmeal, was a specific sign of carcinoma of the stomach. While the stomach might contain hosts of bacteria, there were only three others than that which formed lactic acid that were of importance as pathogenic organisms. First, the sarcinæ ventriculi which indicated insufficient stomach muscle due to non-malignant obstruction. Another was the yeast plant also found in insufficient muscle action. The bacillus geniculatus was present under some conditions in which lactic acid was produced and was considered to be suggestive of carcinoma. A study of the discharges from the rectum was as yet of little value to the surgeon.

**The Surgical Treatment of Bright's Disease from the Viewpoint of the General Practitioner.**—Dr. Alexander Marcy, Jr., of Riverton delivered this address. The term Bright's disease he thought should be dropped entirely from our nomenclature. Reference should be made to the various inflammatory conditions of the kidney that would convey some idea at least of the actual type of the diseased conditions present. After considering the diagnosis of chronic nephritis, and relating to certain cases, he took up the surgical treatment referring first to the successes of Edebohls of New York, Reginald Harrison of London, and A. H. Ferguson, of Chicago, all of whom at about the same time accidentally discovered while operating upon kidneys for other troubles, that some who were afflicted with chronic nephritis became very much better after the operation. The results of their investigations upon the subject warranted them giving the profession a new method of treating these heretofore hopelessly incurable cases. Decapsulation of the kidney was an established fact, and was a legitimate method of procedure in this disease. At present it was looked upon by many as a method of treatment to be used only after all other measures had failed. This was certainly not giving the operation a fair chance to demonstrate what it could accomplish. The question naturally arose how were you going to recognize the disease in the earlier stages and give your patients the advantage of the operation. This could only be done by a systematic, careful, and frequent examination of the urine. If, in a given case, one found albumin or casts, or any other abnormality, one should watch such a case carefully, and if it did not improve speedily under proper medical treatment, operation should be resorted to at once. He firmly believed that before another decade in medicine had gone by the surgical treatment of chronic nephritis would be the acknowledged method of dealing with such cases.

**Ectopic Gestation.**—Dr. Edward Staehlin of Newark read this paper in which he considered the definition and causation as cited by Kelly and other eminent authorities, the clinical history of cases falling under his own observation, the symptomatology inferred from these cases and his own opinion as to the causative influence of the passage of uterine sounds and the ingestion of drastic medicines. He said that the factors which lead to the arrest and developments of the fertilized ovum within the oviduct were usually of a mechanical nature; these factors might be included under the following general heads: (1) Obstacles within the lumen of the tube by means of which its caliber was diminished; (2) diseases of the tubal walls and peculiarities in its anatomy or forms; (3) factors acting externally to the tube by means of which its lumen was encroached upon or obliterated. Two cases cited by him had been most fertile for thought. He said that if it was true that fertilization occurred in the tube, and that the fertilized ovum was carried to the uterus by the action of the cilia, and its safe deposition into the uterus depended upon an unobstructed course, it was equally true, in absence of any obstructive cause, that the irritation caused by the passage of a uterine sound or the turgid effects of drastics, might very well cause peristaltic action of the tube of a nature so violent as to cause its rupture. He felt confident that many cases of so-called severe uterine or ovarian colic, and pelvic cellulitis and hematoma, were cases of ectopic gestation with early and slight hemorrhage, and he felt equally confident that the majority of these cases had as their exciting cause at least the introduction of a uterine sound, or the ingestion of drastic medicines.

**Prophylaxis in Gynecology.**—Dr. Geo. H. Balleray of Paterson read this paper, and made the following summary: Prophylaxis in gynecology demanded that our girls should be properly fed and clothed, take sufficient exercise in the open air and receive proper instruction in regard to the functions of their generative organs. It demanded that our women should receive proper treatment during pregnancy and labor. It demanded that all lesions of the genital tract occurring during labor, should be promptly and skilfully repaired, in order, as far as possible, to close all avenues of infection during the puerperium, and prevent the prolapse of the pelvic viscera which follows almost to a certainty, in all cases of neglected laceration of the pelvic floor. The repair of lacerations of the cervix at an early date, would prevent erosions, cervical and corporeal endometritis, subinvolution, version, flexions, and catarrhal salpingitis; and cancer of the cervix would be almost unknown. Preventive gynecology demanded that gonnorhea in the female should be promptly and efficiently treated in the early stage to prevent its spread to the deeper organs of the pelvis. It demanded that a sensible hygienic mode of dress should be substituted for the fashionable abominations with which the modern woman is prone to constrict, hamper, and deform her person. It demanded that medical students should have an opportunity to study gynecology clinically—that is at the bedside—not from the last row of benches in the amphitheater of a hospital, with the patient at such a distance as to require the use of an opera-glass. Finally, it demanded that the rank and file of the medical profession should be imbued with the desire to acquire a practical knowledge of the diseases of women, in order that the family physician might be able to detect

early all conditions requiring operative interference and refer the patient to a skilful operator, and, at the same time, should have sufficient confidence in his own judgment to oppose the present tendency to the performance of unnecessary mutilating operations in cases in which they were not indicated. When this had been accomplished the general practitioner would find that he had been restored to the honorable position which he once occupied, that of a trusted friend and counsellor; and that he could no longer be looked upon merely as a go-between to steer the patient to his favorite specialist. A more thorough knowledge of gynecology would enable the family physician to appreciate the difference between the real specialist, the honest, intelligent, well-educated, conservative man, who looked at every case with an eye singly to the good of the patient and the *soi disant* specialist whose ignorance of pathology, of the natural history of disease, and of the reparative powers of nature caused him to see in every case an indication for operation, and who was ever willing to sacrifice the interests of the patients to his own unhollowed lust of gain, or undying love of éclat.

Dr. Philander A. Harris of Paterson said that during the preoperative days about three-fourths of all cases of tubal gestation ended fatally. He presented eight specimens of unruptured tubal pregnancy.

Dr. Balleray of Paterson believed that there were thousands of deaths from ruptured extrauterine pregnancy in which the condition had not been recognized. He advised that one should not wait until the classical symptoms appeared before resorting to operation.

Dr. George C. Laws of Paulsboro referred to the process gone through in fecundating the roe of shad in covered pans in which they swelled enormously, even to the size of a currant. If the same process occurred in the fecundated ovum which was in the tube, he did not wonder that rupture occurred.

Dr. F. B. Gray of Jersey City had operated upon eight cases within the past few months, and prior to that time he had never met with a case. He was impressed with the experience of Dr. Harris in being able to report 12 cases of unruptured tubal gestation.

Dr. Herman C. Bleyle of Newark said that the diagnosis of this condition was not, as a rule, made until rupture had occurred.

Dr. Philip Marvel of Atlantic City reported a case of ectopic gestation in which a diagnosis of intestinal obstruction was made merely on the one symptom of excessive and uncontrollable vomiting.

Dr. E. J. Ill of Newark doubted the statements of Dr. Harris that the specimens presented were truly cases of unruptured tubal gestation. Microscopical evidences were lacking to prove this assertion.

Dr. Harris offered to have a microscopical report of the specimens presented at the next meeting, if Dr. Ill so desired.

**Uremic Surprises.**—Dr. J. T. Wrightson of Newark read this paper, which was discussed by Drs. Ellis W. Hedges of Plainfield, Henry Mitchell of Asbury Park, William H. Murray of Plainfield, N. L. Wilson of Elizabeth, and Emery Marvel of Atlantic City.

**Weaning.**—Dr. Floy McEwen of Newark read this paper, and said that weaning was imperative when tuberculosis was present or developing in the mother, when the mother was a degenerate or became insane during pregnancy, when the mother's milk failed and the ordinary methods of treatment did not improve it, and in those mothers who had uncontrollable tempers, or who were unhappy in their homes, or who were unwilling to nurse their babies, or who were irregular in their habits of diet, and rest, and exercise; such mothers gave no promise of successfully nursing their children. In fact, they would do their children incalculable harm if they attempted to do so. Nervousness in the mother was transmitted to the child, and it was utterly hopeless to attempt to nurse a baby from a nervous mother. He said that weaning might become necessary when the mother had to work out for a living, when the baby failed to gain or was losing in weight, in persistent fissures or ulceration of the nipples, in puerperal eclampsia, in persistent fretfulness in the child, and when persistent digestive disturbances in the child indicated a hopeless disproportion between the proteids and fats of the mother's milk. Weaning should be avoided in hot weather, during or immediately following an acute illness, when the child was actually teething, and during the presence and continuance of vomiting and diarrhea, unless such disturbance was directly caused by the faulty milk of the mother.

Dr. D. E. English of New Brunswick reported a case of a mother who had diphtheria and nursed the infant throughout without injury. This was before the days of antitoxin.

**Recent Progress in Cerebrospinal Meningitis.**—Dr. Frank W. Pinneo of Newark read this paper, in which he summarized the present status as follows: (1) Cerebrospinal fever is always due to the diplococcus intracellular meningitidis of Weichselbaum; (2) primary meningitis, whether epidemic or sporadic, is due to this infection; (3) the channel of its entrance into the organism is unknown; (4) lumbar puncture is the best means of diagnosis, and the only certain means; (5) there is no specific treatment; (6) diphtheria antitoxin is useless; (7) in treatment, the most used means are, first, careful attention to hygiene, including much fresh air, and feeding the patient, then lumbar puncture, hot baths, and opium. As the treatment is mainly symptomatic, many other drugs and measures had their advocates.

Dr. R. C. Newton of Montclair said that personally he would be inclined to recommend the use of the hot baths, salicylate of sodium by rectum, bromide and chloral to quiet the pain and restlessness, lumbar puncture to relieve the pressure symptoms if urgent, and to confirm the diagnosis, plenty of sunlight and fresh air, bandaging the eyes if photophobia was present, and, in any case, not allowing the bright light to fall upon the retina, ice to the head, and, perhaps, sinapisms to the spine and extremities, and heat to the feet when indicated. The alimentary tract was to be kept free. A large quantity of water, perfect quiet and seclusion, and handling the patient as little as possible, all would aid in the patient's recovery.

Dr. George E. McLaughlin of Jersey City believed that until we had further knowledge of the means of communicability of this disease we should treat it as we did infectious diseases.

Dr. William M. Leszynsky of New York believed that many cases had been registered with the Board of Health as cases of cerebrospinal meningitis which were not cases of this disease. He emphasized the fact that the first lumbar puncture should be for diagnostic purposes only. He had seen patients presenting violent types of the disease, who recovered without any sequelæ whatever, and he had seen mild types that ended fatally within three or four weeks; therefore, he did not think we had any right to offer a prognosis. He emphasized the importance of fresh air and the subcutaneous injection of ergot. The latter agent took the place of morphine, and rendered the patient more comfortable. He called attention to the dangers attendant upon the removal of large quantities of fluid at the first lumbar puncture.

Dr. John C. Johnson of Blairstown related the history of an epidemic in which there were strong evidences of the infectiousness of the disease.

Dr. Simon Baruch of New York spoke of the controlling influences over opisthotonos by the continuous baths at a temperature of 98° F. given in connection with large doses of salicylic acid.

Dr. Frank D. Gray of Jersey City referred to the alkalinity of the normal cerebrospinal fluid, which became slightly acid in inflammatory conditions. In one case he gave a patient 60,000 units of antitoxin within five days. The fluid was at first acid; the second puncture showed

the fluid to be neutral, while the third showed the fluid to be slightly alkaline in reaction. At the first puncture the fluid was turbid, at the second less so, while at the third it was clear. During this time the symptoms had not abated at all.

**Clinical Diagnosis of Early Tuberculosis.**—Dr. S. A. Knopf of New York opened the symposium with a demonstration of the method of value in making a diagnosis of tuberculosis in its early stages, demonstrating at the same time on a patient the methods employed by him.

**Treatment in Sanatoria and Home.**—Dr. I. H. Hance of Lakewood read this paper. He emphasized the fact that tuberculosis was curable. Osler gave the percentage of healed pulmonary phthisis at 7.5, Biggs 30. He personally knew twelve physicians who positively had tuberculosis, and eight of them had remained cured of their disease for thirteen years or longer, two for twelve, and two for ten years. This was his own personal clinical proof of its curability among his confrères alone. He believed that to-day the sanatorium was the best that we could offer for its patients. A little blood spitting should be always considered as direct evidence of the tuberculous trouble unless one could positively see a ruptured vessel as the cause for it. The open-air rest cure embodied the principles of the treatment; fresh air in the open as many hours as possible in the twenty-four, fresh air inside of house day and night, rest in the open air, superabundance of good food, exercise only as it did not produce certain positive symptoms, and a proper attention to the skin by bathing and the general laws of hygiene. Rest must be absolute in all cases of hemorrhage, when the temperature is above 101° F., where the heart's action is over 100, when there was a daily chill, during the first few weeks while you were observing the types of disease in pleuritic cases when cough was increased by moving about, or when some fluid was found in the pleural cavity, when the patient continued to lose flesh, or under treatment remained stationary well below the average weight. Alcohol and tuberculosis were antagonistic, and the physician would find a very small proportion of cases in which it was indicated. One should avoid over-fatigue, and not neglect the question of bathing. The laws pertaining to hygiene must be carefully looked after. Drugs should be prescribed only when there was a distinct indication for their use. Success in treating tuberculosis rested upon a tactful, sympathetic, and painstaking manner of the physician in his dealings with his patient, and in the constant care and personal supervision of the latter's daily life.

**What the State Is Doing for Her Consumptive Poor.**—Dr. C. J. Kipp of Newark read this paper, and said that the movement for the proper care of the consumptive poor by the State was started by Dr. Halsey in 1900, when he strongly urged the society to take up the fight against tuberculosis, and to appoint a committee with full power to study the questions involved in the effort to eradicate this disease, to draft a proper measure for the erection of an institution for the care of persons afflicted with this disease by the State. His recommendations were favorably received, and a committee appointed to carry them out. While this committee was not able to report any flattering progress, it felt that it had accomplished a reasonable amount of success, and that the prospects for the future were very encouraging. The State of Massachusetts had built a sanatorium at Rutland for about 200 patients, and they had adopted a similar plan and had had the superintendent of this institution, who had been there for five years, go over their plans and point out the defects and suggest improvements. Their plan was thoroughly approved of. From what he had stated it would be seen that, while the people of this State owed a debt of gratitude to the members of this society for having taken the initiative and for having persistently urged the members of the legislature to undertake the care of the indigent consumptive for the State, a great deal of the credit for inducing the members of the legislature to make the necessary appropriation for the purpose of carrying out the plans made by the society was due to the Hon. Franklin Murphy, lately Governor of this State, who on every similar occasion with untiring zeal urged the members of the legislature to appropriate sufficient money to build the sanatorium till it was done.

**The Prevention of Consumption.**—Dr. T. W. Harvey of Orange read this paper, and in conclusion said that it was only by enlisting all possible aids in this campaign that he could overcome the ravages of this disease, the prevention of which resolved itself into two methods; first, the restriction of the danger of contagion due to contact, by the destruction of the bacilli after they had left one individual and before they had reached another. To do this we needed the most efficient public sanitation for the destruction of the breeding places of the disease, the safeguarding the food supplies of the people, by exterminating bovine tuberculosis, and by the prevention of the pollution of food and water and commonly used utensils of the tuberculosis patient. We also need the most careful and conscientious efforts on the part of the diseased individual himself, not to be a source of danger to others, and the intelligent aid of philanthropy in providing treatment and assistance for the indigent. Second, the development of the resistance of the individual, by placing him in an environment conductive to the highest physical condition, and the cultivation of his natural immunity to its highest degree, and the use of such methods as would induce an acquired immunity during times of greatest susceptibility or exposure.

**Some Points in the Diagnosis and Treatment of Pulmonary Tuberculosis.**—Theodore Senseman read this paper. He said that among the objective and subjective signs which first directed our attention to the lungs, and which when present should arouse our suspicions of the beginning tubercular lesion in the pulmonary tissues he considered under six heads as follows: Gradual loss of weight, emaciation; weakness on slight exertion; increased frequency of the pulse after exercise; daily variations in temperature; cough; expectoration. A consideration of the treatment of pulmonary tuberculosis naturally resolved itself into two general parts, that with drugs, and that with remedial agents other than drugs. The day for treating phthisis after the formula of a barrel of whisky, a barrel of cod liver oil, and a barrel of creosote was passed. The tuberculin treatment he condemned. Bathing, rest, and an abundance of nourishing food, fresh, dry air and sunlight were important factors in the treatment. The best food for the consumptive consisted of eggs beaten raw and milk. The value of sunlight and an abundance of fresh air was too well recognized to need any comment.

Dr. Simon Baruch of New York called attention to the necessity of stating exactly the temperature that was required for the water in giving baths.

Dr. Theodore W. Corwin of Newark wished to hear discussed the value of fat as an element of food in tuberculosis.

Dr. S. A. Knopf of New York said that he allowed his patients to exercise when he knew just exactly how much they could stand, the temperature being his guide. Breathing exercises were of value not only in the cure but in the prevention of tuberculosis. Creosote had ruined more stomachs than any other drug in this disease, he believed.

**Oration in Medicine.**—Dr. Richard C. Newton of Montclair took up the consideration of modern neurology, reviewing its history and present status, and paying particular attention to the neuron theory. His excuse for having chosen such a subject for his oration must be found in its great inherent interest and the prospect that in its future study we were drawing nearer to the solution of many questions of paramount importance bearing upon human life and development. Dr. Newton gave a short résumé of the more striking features of the literature of the past year, and he felt sure that this would convince

them of the truth of the assertion that excellent progress had been made in neurology.

**Is the Mosquito the Only Etiological Factor in Malaria?**—Dr. J. T. Wyckoff of Leonia presented this communication. He said that certain facts seemed to indicate that there might be a method of human infection other than now known to us. Such work as railway building, or excavating for sewers, was often followed by a severe outbreak of malaria, when the region was particularly uninhabited before the coming of the workmen. Again on the west coast of Africa, in India, and other tropical regions, we found localities uninhabitable for mankind by reason of the malaria. If malaria was necessary for the continued life of the parasite, and if the mosquito could obtain the parasite only from man, he asked where the mosquitos obtained their abundance of infected material in the absence of man. In explanation of the first difficulty was given the supposition that the soil might be impregnated with the black spores of Ross, which did not decompose but lived a long time, or infected sporozoites might have been deposited in the soil by mosquitos now dead. Thus in disturbing the soil these dormant parasites were set loose, and so in the air gained admittance into the lungs through the blood, or in a similar manner by water into the digestive tracts, and so in the blood. The second question might be answered in three ways. First, the malarial parasite might be capable of living in a variety of vertebrate hosts, so that it might be that an appropriate vertebrate with an appropriate mosquito had the ability to keep the parasite alive. Second, the malarial parasite might be capable of passing from mosquito to mosquito without the aid of man. Third, the mosquito might obtain the parasite from an entirely different source, as an ameba found in the algæ upon which the larvæ feed, as we find certain amebas wherever the anopheles breed. The amebas being taken in by the larvæ change some of their characteristics as they change their surroundings. The latent phase of the disease showed that the parasite could exist in a changed form in man. As had been shown, the first home of the parasite was in the mosquito, and was conveyed to man by the mosquito, hence it was only logical to say that there must be a source for the parasite other than man, for one could not believe that this parasite developed spontaneously in the mosquito.

**The Essentials in Diuretic Treatment.**—Dr. Alexander McAlister of Camden said that, generally speaking, diuretics were indicated in all kidney diseases, as well as in all morbid conditions of other parts of the genito-urinary apparatus. Diuretics could not be employed in the haphazard style that purgatives were often administered. Strictly speaking, a diuretic was always a local-acting drug, though it might be indirectly local through the medium of the blood or the vessel walls. The kidneys occupied an intermediate position between the other two great emunctories, the intestines and the skin. No increase or decrease of functioning was possible in one of these organs without disturbance in the other. When the bowels were loose, or the sweat glands active, stimulation of the renal function was not possible. Tissue metabolism was neither increased nor diminished by the diuretic treatment, save only as a thorough cleaning out of the smoke-stack made an engine consume coal more rapidly. In the selection of diuretics increasing preference was given to the simplest remedies. They suffered comparatively little or no change in passing through the alimentary canal, and did not disturb the process of digestion, but rather stimulated it. The bowels should receive attention before the diuretic treatment was inaugurated. The special diuretic power of water was to be added to that of the remedies selected. When diuretic treatment was instituted to remove accumulated fluids, water had to be eschewed as far as comfort would permit. In nephritis and grave cardiac disease, every diuretic treatment would fail. The remedies to be blended in order to prepare an ideal mixture were buchu with one or more members of its family, one of the vegetable acid salts, a nerve sedative for a corrective, and an ether to aid diffusion. When a distinct astringent was indicated, preference was given to uva ursi. If for any reason the volatile diffusible effect was called for, oil of juniper might be added to the remedies already indicated. No synthetic or inorganic remedies, new or old, approached this in general utility and reliability.

D. F. H. Sherk of Camden discussed this paper.

**Properties of Medicinal Plants.**—Dr. Henry Chavanne of Salem read this paper.

Dr. Joseph Tomlinson of Bridgeton said that notwithstanding that scientific medicine was based upon the action of drugs, we probably had only two specifics, quinine for malaria, and mercury for syphilis. On the other hand, the serum treatment could claim almost as many specifics as could drugs. It was conceded that serum was almost a specific for diphtheria as well as for tetanus. After all, he believed that prophylaxis would be the treatment of the future.

**Some Uses of Adrenalin in the Peritoneal Cavity.**—Dr. Emery Marvel of Atlantic City read this paper, in which he advocated adrenal extract in the treatment of shock, post-partum hemorrhage, and acute peritonitis.

**What Osteopathy Demands, How Shall the Medical Profession Regard It?**—Dr. Philip Marvel of Atlantic City, after having briefly considered the history of osteopathy, which he said was but a part of mechanotherapy, whose benefits had been known to medicine for hundreds of years. He said that the people should be shown that to permit the practice of medicine or of the healing art by any sectarian school meant the establishment of a lower order of efficiency. We must not retrograde. He recommended such legislation as would be fair and just alike to all—legislation which should include the embodiments of all scientific truths touching upon or allied to the relief of all diseases. He recommended that the profession urge a restriction of privileges to a degree at least that would insure against individual injury. That the practitioners of osteopathy and allied systems be prohibited practising in contagious and other febrile diseases, obstetrics, and gynecology, and in those accidental and otherwise acquired sudden illnesses that resulted from chemical poisoning.

Dr. W. Blair Stewart of Atlantic City thought that the suggestion offered by Dr. Marvel promised the only solution. The osteopaths were bound to have representation, and this should be allowed them providing the same qualifications were exacted as were exacted of the regular practitioner.

Dr. Dowling Benjamin of Camden, Dr. Linn Emerson of Orange, and Dr. E. L. B. Godfrey of Camden discussed the paper.

**Treatment of Convergent Squint in Young Children.**—Dr. Linn Emerson of Orange read this paper.

Dr. N. L. Wilson of Elizabeth, Dr. Charles J. Kipp of Newark, and Dr. Walter B. Johnson of Paterson, discussed the paper.

**Report of the Committee on Legislation.**—Dr. L. M. Halsey of Williamstown presented this report, and said that during the session of the last legislature there was introduced a bill to license osteopaths. The committee succeeded in getting a hearing on the bill. A canvass of the Senate after the hearing showed a decided majority against the measure; but, a few days before the close, a substitute bill was introduced which was worse in its provisions than the former bill, and this passed the Senate by a large majority. This bill was then reported to the House, but never saw the light of day. The committee said that the society should decide as to what plan was the better one, to radically oppose them, or to admit one of their members as examiner on the present medical examining force.

**Officers Elected.**—*President,* Dr. Henry W. Elmer of Bridgeton; *First Vice-president,* Dr. Alexander Marcy Jr., of Riverton; *Second Vice-President,* Dr. Edward J. Ill of Newark; *Third Vice-President,* Dr. David St. John

of Hackensack; *Corresponding Secretary,* Dr. Daniel Strock of Camden; *Recording Secretary,* Dr. William J. Chandler of South Orange; *Treasurer,* Dr. Archibald Mercer of Newark. Place of meeting, Atlantic City, in June 1906.

## AMERICAN NEUROLOGICAL ASSOCIATION.

*Thirty-first Annual Meeting, Held in Philadelphia, June 1, 2, and 3, 1905.*

(Special Report to the MEDICAL RECORD.)

(*Continued from page 38.*)

THE PRESIDENT, DR. WILLIAM G. SPILLER, IN THE CHAIR.

SECOND DAY, FRIDAY, JUNE 2.

**Brain Tumors: A Study of Clinical and Post-Mortem Records Bearing on Their Operability and Their Symptomatology.**—Drs. GEORGE L. WALTON and W. E. PAUL of Boston presented this communication, which was read by Dr. Walton. They divided their autopsy cases into three groups, the operable, the inoperable, and the doubtful, or possibly operable. They found the proportion of undoubtedly operable growths much lower than in previous statistics. It was rare to find deep-seated tumors of such character as to be operable. Localizing symptoms were quite apt to fail in operable growths springing from the dura; therefore, as a general rule in exploratory operation it would seem that search should be extended over the surface rather than into the substance of the brain. The authors had studied 221 cases in specimen or autopsy records; 7 per cent of these were operable, 80 per cent inoperable, and 13 per cent. doubtful. By further exclusion the operable cases were reduced to 3.6 per cent. Many of the operable cases showed the tumor in the periphery of the brain. The procedure of puncture of the brain in search of a tumor was not to be encouraged. Gumma had seldom been found in recent years at autopsy, although it was often diagnosed. One should not fail to operate in a given case because the symptoms were just like those of a previous case which was found inoperable. There was headache with vomiting in ninety-one cases, headache without vomiting in sixty-five, vomiting without headache in eleven. Every kind of pupillary reaction was found. In 123 cases the knee jerks were increased, and in twenty-seven were diminished or absent. In thirteen cases the knee jerk was increased on the side opposite the tumor, and in one case on the same side. A further study of the influence of the brain on the reflexes should be made. In cerebellar tumors the knee jerk was increased in five and diminished in four. In certain cases a loss of knee jerk might be due to hypertension, resulting from increase in cerebrospinal fluid.

**The Results of Operation for the Removal of Cerebral Tumors.**—Dr. PHILIP COOMBS KNAPP of Boston presented this paper. The statistics of 828 cases, including fourteen unpublished cases, on which an operation for removal of tumor of the brain was performed were presented. In 471 of these cases, the tumor was wholly or partly removed; 128 of these patients died as the result of operation, and 78 were not benefited. In 189 cases the tumor was not found at the point of operation. In 64 cases it was impossible to remove it, and in 104 cases the operation was for the relief of pressure. Of the whole 828 patients, 265 died as the result of operation, and 186 were not improved. One hundred and sixteen were classed as recovered, but the cases of actual complete restoration to health were regarded as exceedingly rare. A comparison of the statistics of operation collected by the writer on four different occasions in 1889, 1891, 1899, and 1905, showed that there had been a diminution in the mortality and an increase in the number of cases benefited, due to the improvement in surgical technique. The percentage of failures to remove the tumor largely on account of incorrect diagnoses, showed comparatively little gain. The palliative operation for the relief of headache and optic neuritis by relieving intracranial pressure was often unsuccessful. These symptoms were perhaps of toxic origin. In 36 out of 104 cases the headache continued and the optic neuritis increased.

Dr. E. W. TAYLOR asked Dr. Walton what criterion he used in determining whether the knee jerk was increased or diminished, saying that we must have knowledge of what is normal to the individual before it would be possible to decide as to the presence of an abnormality.

Dr. W. M. LESZYNSKY of New York referred to a patient with an endothelioma of the dura the size of an egg, who had been entirely well for six years since operation.

Dr. CHARLES K. MILLS of Philadelphia had always understood that the admission of the presence of a cerebral reflex was an old matter. Huxley called attention to it years ago. There were certain definite responses in the form of knee jerk and Babinski from stimulation of parts of the cortex by tumors and in other ways. In one case of tumor in the parietal region, exaggerated knee jerk was gradually developed as the tumor extended forward. In cases in which there was no exaggeration of the knee jerk, the absence of it might be due to some toxic cause. He thought that the ability of the neurologist to locate the tumor properly had greatly increased within the last five years.

Dr. M. ALLEN STARR said that Dr. Walton's statistics were very valuable, although they ran counter to the old ideas of knee jerks. He considered Walton's explanation of the loss of knee jerk by increased pressure of cerebrospinal fluid to be a good one. In the recent epidemic of cerebrospinal meningitis in New York he had found in many cases lost knee jerk returning on lumbar puncture. In tumor of the cerebrum, one might get symptoms of cerebellar tumor, due to the downward pressure upon the cerebellum, pushing it with force into the foramen magnum and against the bony walls of the cavity in which it lay. Inasmuch as the brain tumor was absolutely hopeless without operation, he believed that at least a palliative operation should be undertaken in every case, for, even if the tumor was not revealed, good results were often obtained. Dr. Starr emphasized his belief that the operation was perfectly safe in the hands of a good surgeon, and stated that he would always advise operation in case he could say who should operate. He had two patients who were absolutely well, one six years after the removal of a sarcoma, and the other from whom an endothelioma was removed on March 1 of the present year.

Dr. H. M. HOPPE of Cincinnati said that he had two cases which had made good recovery from operation performed in 1893. One patient suffered from hemianopsia and blindness, and the tumor had eroded the skull and protruded in the occipital region. This patient now, following operation, had paraplegia and one or two epileptic attacks a year. The other case was one of sarcoma of the motor area.

Dr. MEYER said that in connection with the study of the effect of the brain upon the reflexes, it was necessary to remove the spinal cord at autopsy in order to determine whether or not any lesions existed in it. He found in one case of cerebellar sarcoma that the lumbar cord was also involved. He would agree with Starr rather than with Knapp as to the advisability of operation in doubtful cases. He recently had a case in which no operation was done, but at autopsy it was found that the case would have been easily operable. The patient had the Babinski sign, but the tumor was found over the sensory speech area.

Dr. B. SACHS thought the changes in reflexes of cerebral tumor were often accounted for by cord and root changes. He reported a case of glioma, removed ten years ago, not entirely well except for occasional numbness in the right hand. He thought the palliative results were good enough to warrant operation, but he wanted to select

his surgeon. Surgeons had not given due attention to the technique of operation for brain tumor, doing their operations now very much as they did ten or fifteen years ago. Surgeons could give more help than they did. The ability of neurologists to diagnose and locate tumors properly had greatly increased. If the tumor was not found it was because its localization by the symptoms was an impossibility.

Dr. Harvey Cushing of Baltimore stated that he was in favor of early operation. The usual delay for therapeutic diagnosis between gumma and other forms of tumor was a very serious one, and led to a discrepancy between diagnosis and autopsy findings. Potassium iodide often improved the symptoms of tumors other than gummata. Even as a palliative measure, a large flap should be raised, a small one being of no benefit. By proper means, hemorrhage during operation could be controlled. In the past three years, at Johns Hopkins, he had had only one operative fatality, which was in the case of an extremely large tumor in a child, and had had only one fungus cerebri. Hernia frequently occurred in palliative operation, but should never become a fungus under proper care.

Dr. Walton, in closing, stated that when there was unilateral alteration of the knee jerk, he took the other side as a criterion in case it seemed to be normal. An examination of the cord was important, but was not always necessary.

Dr. Knapp, in closing, said that he would not admit certain cases as recovered, though so regarded by others. He emphasized the fact that complete recovery seldom occurred. His statistics showed that there had been a fall from 25 per cent. to 4 per cent. in operative fatality. He did not mean to imply that palliative operation should not be undertaken. He only emphasized the fact that it was often unsuccessful.

**The Motor Area of the Human Cerebrum as Determined by Cortical Faradization, with a Discussion of the Surgery of the Motor Region.**—Dr. Chas. K. Mills and Dr. Chas. H. Frazier presented this communication. The paper was illustrated by several diagrams. One represented the position and general outlines of the motor region and the subdivisions of the area for the face and upper extremity, several of these having been determined by faradic investigations of the cortex; another indicated the exact method of passing to and fro between the postcentral and precentral convolutions until a minimum standard current was obtained, and others illustrated the exact methods of surgical procedure in exposing the motor cortex and also the results of investigations on the cadaver demonstrating the accuracy of the plans employed. In all operations large openings were made, and these were of the osteoplastic type. In the paper extensive references were made to personal experiences, many of them recent, but some reaching back as far as 1888. A series of unpublished cases of Dr. W. W. Keen, and also of Drs. Mills, Frazier, and Spiller were given in abstract. A historical résumé of the American and foreign literature of the subject was made, beginning with the case of Bartholow, in 1874, and including cases both by neurologists and surgeons. The authors discussed the observations of Grünbaum and Sherrington on the chimpanzee and gorilla, comparing their findings with those of Ferrier, Horsley, Schäfer, Beevor, and others on monkeys below the anthropoids. Papers of Lamacq, Rothmann, and Krause were considered. The readers of the paper took a strong stand in favor of the view that the motor zone was located entirely, or almost entirely, cephalad of the central fissure. The methods of operating for the relief of brain lesions employed at the hospital of the University of Pennsylvania were detailed and illustrated by the presentation of a patient who had recently been operated upon for a cyst in the motor region.

Dr. James Hendrie Lloyd of Philadelphia said that as one of the pioneers in this work, beginning 17 years ago, he had followed the paper with great interest. The tabulation by Mills was open to some errors. He did not think that the results of faradization at operation were very reliable, because of the difficulty of localizing the central fissures. He thought the results which he obtained from faradization of the postcentral area were fairly reliable. A difficulty in faradization was to limit the transfusion of the current. The authors of the paper had shown a preponderance of evidence in favor of the limitation of the motor area to the precentral convolution, but he did not think that they had proved their case.

Dr. B. Sachs commended the standard osteoplastic flap used by Mills and Frazier. Since 1890 he had had about 40 operations upon the motor area, and had not once omitted faradization. He had found dural faradization with the bipolar electrode very satisfactory for the purpose of localizing a tumor or cyst, but did not claim that it was good for physiological purposes. He had had much experience with faradization, but had not published his results.

Dr. M. Allen Starr stated that since 1888 he had used faradization of the motor area as a matter of routine in cases of operation for epilepsy, but had not used it in cases of tumor or cysts.

Dr. Harvey Cushing stated that when he was in Liverpool, he had assisted Sherrington and Grünbaum in their experiments upon the anthropoid apes. Since then he had faradized the cortex in all favorable cases at the time of operation. He did not think the results were reliable when a cyst or a tumor was present. He had had 50 cases of faradization of epileptics, and had never obtained motor responses except in the precentral convolution. The best way to test the strength of the current was to apply an electrode to the temporal muscle which was always exposed. He had never succeeded in opening the leg area and said he would be pleased if anyone would explain how it could be done. The leg area was very high and close to the great longitudinal fissure. It was covered by the adhesions of the Pacchionian granulations and was unapproachable operatively. Dural stimulation was useless. Cortical stimulation was useless unless one first evacuated the cerebrospinal fluid in order to prevent diffusion. The consideration of the influence of the anesthetic was very important. He always used the unipolar electrode and put the indifferent electrode upon the side of the operation. Scalp measures were of no value except to the amateur. Anyone with experience could pick out the motor strip without elaborate measurements.

Dr. D. J. McCarthy said that for practical purposes the bipolar electrode was good enough, but for physiological purposes the unipolar was necessary. Anesthesia and shock were very important factors. The strength of the current must be increased as these conditions deepened. Care must be exercised in the manipulation of the brain. After faradization in animals there was a tendency to hemorrhagic encephalitis. Diffusion of the current could be obviated by puncturing the dura with an electrode.

Dr. Charles K. Mills, in closing, stated that faradization in the presence of a cyst or tumor would depend upon the situation of the new growth in the opening. In one case the tumor was very far forward and the motor area was not involved. This was also true in the case of a cyst. Faradization also taught something in reference to the depth of subcortical involvement. He had not seen any harm done by faradization in any of his cases. It was not advisable to try to localize by faradization through the dura. He was surprised to hear what Dr. Cushing said about rule of thumb measures on the scalp. He always evacuated the subdural fluid, but did not see how it was possible to remove the fluid from the subarachnoid spaces.

**Postoperative Asthenia.**—Dr. S. Weir Mitchell of Philadelphia presented this subject. He said that one-third of all patients operated upon by abdominal section, were doomed to six months of helplessness after the operation. This could be avoided if care were taken to put the patient into the best possible condition before the operation. After the operation the patient should be put under the care of a

physician. He referred to asthenias following operation in soldiers during the Civil War. Keen, Morehouse, himself, and others, had called this condition acute exhaustion. He often saw men so weak they could hardly stand, and others who could walk only a short distance as a result of heavy marches. There seemed to be great sensitiveness of every muscle in the body, and many months' treatment by surface friction and good diet were required to bring them back to health. In other cases a widespread crop of boils would break out.

**Cerebellar Tumors, with Reference to Diagnosis and Surgical Treatment.**—Dr. B. Sachs of New York read this paper, reporting not merely successful cases, but his entire experience with cerebellar tumors. In the last few years he had had 22 cases in which the diagnosis was certain. Fourteen were hospital cases and eight were private. Optic neuritis appeared unusually early, and soon led to absolute blindness. Paralysis of the external rectus was unusually frequent, and more important than any other symptom. Indirect cranial nerve symptoms involving the first, third, and fifth pairs were very frequent. They were usually unilateral. Very little stress could be put on the deep reflexes. In some they were lost, in others exaggerated. Exaggeration was probably due to pressure on the pyramidal tracts. Cerebellar tumors were difficult to differentiate from those of the frontal lobe. Direct sensitiveness to touch and localization of the headache were not very helpful. The question of the character of the tumor, whether gumma, tubercle, or sarcoma, malignant or benign, was puzzling. In one case where the tuberculin reaction was obtained the tumor turned out to be sarcoma. Localization of the tumor was difficult as localizing symptoms were frequently absent. Facial and auditory nerve involvement occurred when the tumor was in the depth of the cerebellum as well as in the cerebellopontile angle. Of 22 cases he advised operation in 6, in the others there was no sufficiently localizing symptom to warrant operation. Of the six patients, three died in one to two weeks. In none of them was the tumor found. In 2 of the 3, autopsies revealed the tumor exactly at the site diagnosticated. Of the 3 patients living, one improved after a preliminary operation and one after the removal of the tumor. In the third case the tumor was not found, but the man has been able to go about and attend to his business. In spite of the good results obtained by some, Sachs still held to the view that there was not much in the statistics to encourage operation, but we might encourage exploratory operation early.

Dr. F. X. Dercum of Philadelphia said that it was at present a matter of common consent that there was early optic neuritis with blindness in cerebellar tumor. As to external rectus palsy, it would help but little as it occurred in so many tumors in other situations. He had been puzzled in the diagnosis between frontal and cerebellar tumors. In a case, years ago, he advised an operation on the frontal region, and at the autopsy a cerebellar tumor was found. Cerebellar surgery is the least promising of all brain surgery. He asked Sachs if he regarded the lateral lobe of the cerebellum as of importance, saying that neurologists do not agree with physiologists on this point.

Dr. William Hirsch of New York had seen a number of cerebellar tumors in the last few years, and had found early optic atrophy. He thought the symptoms might be accounted for by internal hydrocephalus due to disturbance of the circulation in the ventricles. This also explained why early trephining relieved the symptoms. In some of his cases the brain was distinctly flattened. Mydriasis had been a common symptom in his experience. In localizing, the bilateral external rectus paralysis was of much value. The localization in one of the lobes was made in children by their falling to one side.

Dr. Harvey Cushing said that he agreed with Dr. Hirsch as to hydrocephalus in subtentorial growths, and said that this accounted for the frontal symptoms. Loss of the sense of smell might be caused by tumors anywhere. In cases where the trigeminal nerve had been removed there was no headache on the side from which it was removed, because it supplied nearly all of the dura. He had had three cerebellar cases. One patient operated on died in 6 months of fungus cerebri; another, a child, operated on 13 months ago was well; the third, a child, had not regained cerebellar control.

Dr. Charles K. Mills agreed with Sachs that there were early optic neuritis and blindness, but thought the blindness independent of the neuritis. Only prefrontal tumors were hard to differentiate from the cerebellar. When the motor or speech areas were involved, the diagnosis was easy. Mental symptoms were frequently present in frontal tumor. Headache was more frequent in cerebellar tumor.

Dr. Frank R. Fry of Cincinnati said that he considered the cerebellar attitude of the head and falling to one side important.

Dr. Theodore Diller of Pittsburg reported a case in which there were definite symptoms of cerebellar tumor in which the patient refused operation and was now well.

Dr. M. Allen Starr had had operations on 12 cases of cerebellar tumor without a single success. In no case where the tumor was removed did the patient get well. In one case a flap was removed on each side at successive operations, and a part of each lateral lobe of the cerebellum cut away. No tumor was found. The patient had been fairly well since the operation 1½ years ago. In 10 cases the tumor was inoperable. As to the question of staggering, in 30 cases, two-thirds of the patients staggered away from and one-third towards the tumor. In frontal tumor the early-morning headache and vomiting, lasting 3 or 4 hours, did not occur as in cerebellar tumor. He had seen the cerebellar attitude of the head in two cases. The early symptoms were due to distention of the ventricles.

**Thyroid Metastasis of the Spine.**—Dr. F. X. Dercum of Philadelphia reported the case of a woman who had been admitted to the Philadelphia Hospital in June, 1904, with the history of an operation for the removal of a goitre in August, 1899, by Dr. A. C. Wood, at the University Hospital. She had made apparently a complete recovery from the operation, but about one year afterward she began to suffer excessively from severe pain in the left upper extremity. The pains were sharp and shooting in character. Subsequently, pains made their appearance in both lower extremities, and later in the right upper extremity. She finally became completely paraplegic. When admitted to the Philadelphia Hospital, both legs were in a position of extreme contracture. They were also markedly wasted. Contracture with extreme wasting was also present in both upper extremities. A disassociated sensory loss was also present. Tactile sensation was preserved over the entire body, save that over the left leg a tactile hyperesthesia, existed. Over the trunk, as far as the nipples anteriorly, and as far up as the axilla posteriorly, and over the entire right lower extremity, there was a complete loss of pain and temperature sense. The autopsy revealed a tumor involving the fourth and fifth cervical vertebræ. The tumor involved the dura mater and pressed upon the cord. In its gross appearance, the tumor suggested a sarcoma. Similar masses were found infiltrating the sternal end of the left clavicle and also several of the ribs. A microscopical examination of the growth revealed the astonishing fact that it consisted of thyroid gland tissue. The acini were well formed, lined by typical cubical epithelium, and filled with colloid material. Dr. Dercum discussed the question of thyroid metastasis, and also the question of malignancy. The tumor did not, of itself, show such anomalies of thyroid structure as would justify the diagnosis of a malignant growth. Dr. Dercum also dwelt upon the resemblance of this case to one reported by Gussenbauer in 1891, and to a second reported by Hollis in 1893, in both of which paraplegia and associated symptoms had resulted from thyroid metastasis of the spine.

**Operative Intervention for the Intracranial Hemorrhages of the New-born.**—Dr. Harvey Cushing of Baltimore presented this paper. A few years ago, on studying new-

born children that had died suddenly, he found that in 50 per cent. of the cases death was due to intracranial hemorrhage. The early lesion which presented itself later in life as sclerosis of the brain was little known, and was probably very often due to hemorrhage at or about the time of birth. Many patients with intracranial hemorrhage early in life recovered, and its after effects were seen in the form of birth palsies. The chief symptom was tense fontanelle; asphyxia and early convulsions were important historical facts. The hemorrhage was always venous and was due to laceration in the veins over the cortex as they passed up to enter the superior longitudinal sinus. Often there were no symptoms. Cushing had operated on four cases. The first was one of twins born in difficult labor terminated by forceps. The child was asphyxiated. It was in very bad condition at the time of operation. The entire parietal bone was turned down and extensive hemorrhage was found covering the entire hemisphere, the clot being 1 cm. thick. The baby took the bottle subsequent to the operation, but died the next morning. The second child was operated upon when 8 days old. Convulsions appeared on the sixth day of life, and on the seventh day there were 11 convulsions. The hemisphere was exposed and an extensive clot was found. The child was now 18 months old and was perfectly well. The third case was a very serious one. The child was born in a forceps labor. There was slight cranial injury, and the child was asphyxiated; it nursed 24 hours, but later became stupid and the fourth day there was a very marked unilateral exophthalmos which led to diagnosis of hemorrhage from the lateral sinus. Two days later Cushing saw the child and undertook operation with the idea of removing the eye for the sake of appearance. He determined, however, to undertake the operation for hemorrhage. It was found that the hemorrhage had been from the lateral sinus which later became thrombosed. He exposed the hemisphere on each side to make sure that nothing would be overlooked. The child made a complete recovery. It was now 8 months of age and appeared to be perfectly normal, although it was impossible to determine its exact mental condition. The fourth case was in many respects similar to the first, the child perishing soon after the operation.

Dr. D. J. McCarthy of Philadelphia stated that he had three cases in his collection in which the lesions present showed that hemorrhage must have occurred a long while before birth.

Dr. C. K. Mills called attention to cases of unilateral cerebral palsy which were due to hemorrhage following infectious diseases in which cysts later formed. When hemorrhage into the brain occurred as a result of infectious disease, the patient should be operated upon the same as for hemorrhage due to other cause.

**The Progressive Spinal Atrophies.**—Dr. Charles L. Dana of New York presented this paper. Of the cervical and cervicobulbar (Duchenne-Aran) type he had 19 cases; of the lumbocervical, or leg and shoulder type, 15 cases; of the amyotrophic lateral sclerosis type, 10 cases; and of the bulbar and bulbospinal, 6 cases. Syphilis was the most common cause, being active in 25 per cent. of his cases. He thought that the percentage was really larger than this. Syphilis was the causative factor in 8 out of 19 cases of the cervicobulbar type and in 1 case of the purely bulbar type. This was rarely the cause in the cervical and the amyotraphic type. Occupation was the next most common cause. It was also due to exhaustion, acute infection, lead, and tobacco poisoning. Lead did not have much to do with it, as only 5 of Dana's cases were traceable to lead as a probable cause. Heredity did not play any part in the cervicobulbar type, but was active in amyotrophic cases. The author reported a case of bulbar palsy and another of tabes with autopsy.

Dr. Joseph Collins of New York reported a case of the amyotrophic form which he thought was due to lead, as the urine showed large quantities of this metal.

*(To be Continued.)*

## NEW YORK ACADEMY OF MEDICINE.

Section on Pediatrics.

*Stated Meeting, Held May 11, 1905.*

Dr. L. E. LaFétra in the Chair.

**Case of Friedreich's Disease.**—Dr. Charles E. Nammack said that he had presented a case of Friedreich's disease April 12, 1894, but had not seen another case until April 29, when the patient was admitted to Bellevue Hospital. He was 23 years old, native of this country. His father died of Bright's disease and his mother from change of life. There was no history of any nervous affection in his own family or in the families of his grandparents. The history was also negative regarding tuberculosis, rheumatism, and syphilis. The patient smoked some, but was not a drinking man. He had malaria six years ago. He denied any venereal disease. Five years after an attack of diphtheria he noted some unsteadiness in his gait and a slight trembling of his hands. His memory became impaired. There was some slight complaint of his digestive apparatus. There was no marked trouble with his bladder or rectum. The patient was a well developed and well nourished young man, and his mental condition was clear. There was a slight drooping of the left shoulder girdle. There was neither any atrophy nor hypertrophy of muscles. There was some slight nodding movement of the head, as well as swaying. The pupils were regular and reacted to light and accommodation. There was no strabismus or ptosis and the eye grounds were normal. The thoracic and abdominal organs were found to be normal. There was a marked incoördination, particularly shown in the manner in which he reached out for and grasped a glass containing water; he hovered over the glass and then grasped it, a "bird of prey" movement. There was no loss of power in either extremities. The feet were cold and moist and presented the usual deformity which appeared to be a talipes equinus to a certain extent. Knee and elbow jerks were present. There was no clonus nor Babinski sign. The Romberg sign was marked. The gait was ataxic but was not that of tabes. Dr. Nammack said that these cases were usually mistaken when first seen for other conditions, especially in early childhood, following some acute affection. This was the second case he had ever seen. A peculiar and marked feature in this case was the impulsive and uncontrollable laughter. The peculiar speech was monotonous, not staccato speech of multiple sclerosis.

Dr. L. Pierce Clark said that Friedreich's disease was not such a rare affection as the speaker implied; there were on record now three, four or five undred cases, and at the Vanderbilt Clinic alone four or five cases were seen every year. The speech was very suggestive of an anomalous form of multiple sclerosis. He believed it was a possibility that in addition to the Friedreich's ataxia there was associated a multiple sclerosis ataxia as already had been described. It should be borne in mind that Friedreich's ataxia might be associated with other lesions, especially those of the nervous system as early degenerations. He thought the movements partook of the intention tremor type.

Dr. Henry W. Berg said that some eight years ago he presented a case in which there was a traumatic lateral curvature which was followed by symptoms similar to those described by Dr. Nammack. The patient was a girl 14 or 15 years old; she had a severe fall which was followed by a lateral curvature without fracture of the spine. This curvature rapidly developed, with the primary curve high up and the secondary one well down. At the end of two years there appeared the ataxic gait, there was an absence of reflexes, pains developed similar to those of locomotor ataxia, there was no scanning speech, etc., the patient presenting the picture of a disseminated sclerosis, the sclerosed patches being limited to the spinal cord. At autopsy there was found a sclerosis in the posterior part of the cord, but worse at the point of lateral curvature. Dr. Berg believed that the cord would stand much deviation without undergoing myelitis.

Dr. Jacob Sobel said that the association of this impulsive laughter with Friedreich's disease was new to him, and he had always associated it with multiple sclerosis. At a recent meeting, Dr. Hirsch had presented a case of trauma which was followed by multiple sclerosis, and he said that this sign was not at all common in these cases.

**A Case of Retained Intubation Tube Treated by Gradual Dilatation.**—Dr. Fielding Lewis Taylor presented a child 3 years old who had worn an intubation tube for 187 days.

Dr. Henry W. Berg said that at the Willard Parker Hospital they had had about 27 chronic tube cases within the past four or five years. The longest time one was worn was one year and a half, and they had recently discharged a patient who had worn one nine months.

**Two Cases of Hydrocephalus Treated by Autodrainage.**—Dr. Alfred S. Taylor presented these patients. He said that external drainage had never been satisfactory because of the anger from infection and early death. Methods of internal drainage had been tried, and only those had been successful which dealt with drainage of the ventricle into the subdural spaces, as first tried by Sutherland of England, who used the upper corner of the anterior fontanelle. The patients nearly all died within two or three months. The particular technique of the English surgeon did not appeal to him, and he therefore devised the operation which had already been described at previous Academy meetings. The right side of the head was chosen in order not to endanger motor area or the speech center. The osteoplastic flap was made and turned back, the brain was pierced through the second temporo-sphenoidal convolution, etc. A forty-day chromic catgut was used for drainage, being covered over with Cargyle membrane, leaving the tip of the drain in the ventricle one-quarter of an inch.

Case I.—This was a patient over 5 years old, who was brought from the Randall's Island Hospital and no definite history had been taken. The head was 62.5 cm. in circumference, and the tension was so great that, at time of operation, the brain protruded three-quarters of an inch. Following the operation the temperature went up to 104° and 106° F., which lasted for several weeks. During the first weeks improvement was very slow, but after three months it became moderately rapid. The child had become moderately intelligent and acted more like other children. It was now 26 months since the operation and he could sing, look at books, knew everybody in the ward by name, and there were no evidences of intracerebral pressure.

Case II.—This child was 13 months old at time of operation. She was born with great difficulty, one of her thighs being broken. At the age of 5 months she had a rapid abnormal growth of the head. At time of operation her condition was very good, the reflexes being normal, etc. The head was very large, the eyes protruded so that the sclera showed entirely around the iris. There was moderate nystagmus. The head grew 49 or 50 cm. in nine weeks, almost one-half an inch per week. The operation was done as already described. After eight or ten months the osteoplastic flap had healed by bony union. During the first three or four weeks there was no change in the circumference of the head. About the tenth week the head became asymmetrical, and the right side appeared to be smaller. The eyes were back in the orbit, the nystagmus had disappeared, etc. At the end of eight and a third months there was no incracranial tension. Eleven months after operation the head had grown to 61.5 cm., and the child was beginning to play in her crib. At 22 months after operation it measured 61 cm. In other words, there had been no growth from 11 to 22 months.

Dr. Lewis M. Silver said he had recently operated upon two cases and his results he would report to the Section next autumn. Both reacted nicely from the operation, except that for three days the temperature was 103° F., but it quickly subsided.

Dr. Henry Koplik said that Dr. Taylor's operation practically converted an internal into an external hydrocephalus. The cases on which this operation should be tried, he believed, were those of meningitis with beginning or commencing hydrocephalus. Lumbar puncture was absolutely of no value in these cases. He thought that Dr. Taylor had been given bad material with which to work.

Dr. L. Pierce Clark said he had followed Dr. Taylor's cases very closely and had noted a very decided improvement in both. The improvement seemed to be rather marked soon after operation.

D. L. E. LaFétra had seen the second patient presented by Dr. Taylor, and was considerably struck by the marked improvement.

Dr. Taylor closed the discussion, and said that in neither of the cases were there any evidences of active drainage until three months after operation.

**Intestinal Hemorrhage in a Child Eighteen Months Old.**—Dr. J. Finley Bell reported this case in which he had been able to exclude as causes everything except scurvy and ulcer. The probabilities were that it was caused by an ulcer in some part of the small intestines.

Dr. Henry Koplik said he had seen this case in consultation, and there were absolutely no signs of scurvy except when he squeezed an extremity the patient winced. He thought the case was probably one of scurvy with beginning enteric catarrh. The gums were pale but with no ecchymoses in the extremities or elsewhere. If the case was one of scurvy it was an atypical one. He thought the case taught a lesson that one should not operate on such cases unless there was present tumor and other signs of an intussusception.

Dr. LaFétra wished to emphasize the point that blood in the stools might be one of the earliest signs of scurvy.

Dr. Berg said that he excluded scurvy as a cause when there was but one large hemorrhage from the intestines.

**Some Cases of Congenital Syphilis.**—Dr. Henry S. Patterson reported two such cases. He said there was a general belief that the transmission of syphilis from parent to offspring was a limited process, that in the father the transmissibility of the disease died out after the second year and, in the mother, after the third year. Jonathan Hutchinson had stated that a man might marry at the end of a year if there were no lesions. This impression was held as the result of the observations of most clinicians, in the large majority of the cases, and the principle was considered much more likely to obtain where the parents had had good and continued treatment. Although physicians had occasionally seen syphilis transmitted to children by parents who had allowed the orthodox period of time to elapse between the primary lesion and marriage, and who had been well treated, still such cases were sufficiently rare and interesting to warrant drawing attention to them at present. In the first case reported, the woman had been syphilitic for six years, and at the end of that time was still able to transmit the disease to her child. In the second cases the mother had a primary lesion on the lip in 1898, which was followed by secondary lesions and, in 1899, she had late secondaries and for two years after she was thoroughly treated by an excellent physician. In 1900 she married, and in the fall of 1901 gave birth to a female child which was and has since been perfectly healthy. Shortly after the birth of her first child treatment had been discontinued. On November 28, 1903, she gave birth to a syphilitic child whose lesions healed up in a few days under small doses of gray powder.

**Measures for the Relief of Symptoms in Cerebrospinal Meningitis.**—Dr. Francis Huber read this paper. He said that of the 112 patients treated at Gouverneur Hospital last year (all doubtful cases being excluded) 28, or 25 per cent., recovered, 5, or about 4 per cent., were discharged improved, a similar number were unimproved, and the remaining 74, or about 66 per cent., died. Among 14 of the 28 recoveries, 10 had fully recovered in two weeks or less; 1 was discharged on the 17th day, and the other 3 in about three weeks. These figures were interesting in that it showed that 12 per cent. of the total number of cases treated belonged to the mild type of the disease. During the first 23 days 56 patients died; from the 29th to the 230th day 18 died. In the first 5 days 26 died, constituting 23.2 per cent. of the

total number of admissions, or 35 per cent. of the fatal cases. The deductions from the above might be tersely given as J. C. Wilson had stated: "The mildest cases require no treatment; the malignant react to none. Medicine with all its resources is neither capable of combating the attack nor responsible for its results." In considering the treatment in detail and in estimating the value of any plan, certain factors should not be lost sight of, as, (1) the large proportion of malignant cases; (2) the grave character of the anatomical changes and (3) the great irregularity in the clinical course. It was impossible to predict the subsequent progress from the initial symptoms. An apparent convalescence was frequently interrupted by an unexpected recrudescence or relapse, and severe and apparently grave manifestations might clear up unexpectedly. The treatment was entirely symptomatic. The case should be isolated and placed in charge of a good and competent nurse, and in a well ventilated room. The general nutrition must be sustained. An ice bag to the head, with proper support to head and neck, would add to the comfort of the patient. Plenty of water should be given and the body functions should be regulated. The nasopharynx should not be neglected. Forced feeding through the nose or mouth might be indicated. Pain and restlessness must be relieved by chloral per rectum or morphine per os or hypodermatically. The headache might be relieved with phenacetin, with or without codeine. Ergot in the beginning had been praised. Severe vomiting in the later stages was relieved by lumbar puncture, small hypodermics of morphine, ice to the epigastric region, and careful dieting. If pulmonary edema occurred, sodium benzoate of caffeine subcutaneously given, afforded prompt relief. The general circulation was improved by packs or baths with or without mustard. This lessened the muscular spasm and rigidity in general. Each case presented its individual indications. Nourishment and nursing were of the utmost importance. The iodides were indicated with a view of causing absorption of plastic exudates. Local bleeding by leeches did not give any appreciable results. At the Gouverneur Hospital the first puncture was usually for purposes of diagnosis, a small amount only being withdrawn. Later, larger amounts were taken away. To influence the intracranial pressure from 10 to 15 c.c. must be removed, but care should be taken not to remove more than 20 c.c. or 30 c.c., unless the evidences of pressure were very prominent. Chronic hydrocephalus (internal variety) necessitated autodrainage by Taylor's method. Chronic hydrocephalus (external and internal) repeated tappings at intervals of a few days were indicated. Hypodermoclysis was given early to overcome the prostration and initial shock and possibly to dilute the toxins, later on to supply fluids to the tissues. He said certain clinicians resorted to the diphtheria antitoxin in treating this disease, but it had been found by most of them that it was without value, especially in the experience at Roosevelt Hospital.

Dr. J. Finley Bell reported a case seen in Englewood, N. J., in which the pneumococcus was obtained by pure culture.

Dr. Henry Koplik said that the prognosis in these cases varied with different epidemics and with the age of the patient. The prognosis in those below the age of two years seemed to be invariably fatal. He did not believe that lumbar puncture was a difficult operation, but he had less faith to-day in its efficacy than formerly. It should be remembered that in young children they were unable to express their feelings after a lumbar puncture; it was known that in adults there occurred a severe headache which lasted for some time, and it was Dr. Dana's suggestion that some serum should be injected to replace the fluid removed; Dr. Koplik thought this was a good idea. The subdural injection of drugs he believed to be productive of more harm than good, and the lysol injections he had some time ago given up. During the present epidemic he had seen several cases occurring in the same family, whereas in previous epidemics, this had not occurred in a single instance, so far as he knew.

Dr. Henry W. Berg said that in 1895 the Board of Health of this city, did not know of the existence of such an epidemic until he went and asked if they could supply him with the number of cases that had occurred within the last four months; then it was noted by the Health Department, and not before, that there was an epidemic of cerebrospinal meningitis which had been on the increase; this had been shown by the number of deaths which had gradually increased each month. During that epidemic he had not seen one single instance of two cases occurring in the same family, and in that respect the epidemic was different from the present one.

**Ulcer of the Stomach in Children.**—Dr. Wm. L. Stowell read this paper. (See page 52.)

Dr. David Bovaird, Jr., said that in infants there were several kinds of ulcerations to be seen, the tuberculous, the multiple, the so-called "brown" ulcer which corresponded to the round ulcer seen in adults, etc. The multiple ulcer was what Dr. Northrup had already referred to, and was associated with a distinct gastritis. These ulcerations, as a rule, were not noticed except on very careful examination. Dr. Adriance's observation led him to believe that multiple ulcers were far more common than generally believed, and were so frequently found at autopsies. The round ulcer in children he believed to be very rare, and he personally had never seen a case.

Dr. Foote said he had been struck by the similarity of the symptoms as they occurred in childhood and in adults, and he related a couple of instances, in one of which a child, 5 years old, with peritonitis, was taken to the hospital because of a supposed appendicitis. At autopsy there was found a perforating ulcer of the stomach. In the second case, a girl 12 years old, had suffered for a long time from pain, vomiting, and bleeding. At operation the pylorus was found to be adherent to the small intestine, and so constructed that it would not admit the little finger; there was a dilatation of the stomach, etc. A retrocolic gastroenterostomy was performed, and a good recovery followed. The treatment of these cases in children should be as in adults, and the same results should be obtained.

## College of Physicians of Philadelphia: Section on General Medicine.

At a stated meeting held May 8, Dr. Alfred Hand reported "A Case of Typhoid Fever, with Divers Complications, Including Perichondritis, from which Typhoid-bacilli Were Isolated One Year After the Attack of Typhoid Fever." The patient was a man, about 32 years old, whose illness was complicated by intestinal hemorrhage and by pneumonia. The temperature failing to decline to the normal after a reasonable time, a small focus of suppuration was discovered at the junction of the fourth or fifth rib on the right side with its costal cartilage. A small amount of pus was evacuated by a simple incision, but perfect recovery did not ensue until resection of the rib was practised. Dr. Hand also reported a case of typhoid fever setting in with a chill and presenting symptoms suggestive of pneumonia, and an additional case characterized by toe-drop due to peripheral neuritis and the pressure of the bedclothing. Dr. H. R. M. Landis exhibited a patient presenting "Hypertrophic Pulmonary Osteoarthropathy." The case occurred in a woman with symptoms and physical signs suggestive of a fibroid process in the lungs without tubercle bacilli in the sputum. The extremities of the fingers and toes were enlarged and bulbous, and there was hyperplasia of some of the long bones. The report was supplemented by a full discussion of the clinical and pathological features of the disorder. Dr. Robert N. Willson, Jr., presented a communication entitled "The Value of Kernig's Sign." He pointed out that failure to extend beyond an angle of 120° the leg on the thigh flexed on the abdomen at an angle of 90° is observed in a considerable number of cases of cerebrospinal meningitis, and conversely the phenomenon is

occasionally present in cases in which there is no reason to suspect meningitis. Drs. Clifford B. Farr and William B. Cadwalader presented a communication entitled "The Significance of the Analysis of the Gastric Contents." They showed, among other things, that the acidity of 60 per cent. stated by foreign investigators as normal appears not to be applicable in this country, where a percentage of about 40 per cent. seems to be more nearly the normal. Little difference in the figures was observed with respect to race. Dr. Herbert Fox read a paper entitled "A Comparison of the Agglutinating Properties of Typhoid Fever Sera with Bacillus Typhosus, Bacillus Paratyphosus (A) and Bacillus Enteritidis (Gärtner), with Reference to Their Individual Antisera."

**Contagious Diseases—Weekly Statement.**— Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending July 1, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 632 | 13 |
| Diphtheria and Croup | 235 | 20 |
| Scarlet Fever | 83 | 4 |
| Smallpox | 1 | ..... |
| Chickenpox | 109 | ..... |
| Tuberculosis | 418 | 145 |
| Typhoid Fever | 47 | 9 |
| Cerebrospinal Meningitis | 35 | 22 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1,560 | 213 |

**Clinical and Experimental Observations in the Action of the X-Rays.**—Quadrone, as the result of observations made on patients with leukemia, malignant lymphoma, splenic anemia, and other blood diseases, as well as on animals, concludes that the *x*-rays have a special action on the circulating leucocytes, and perhaps also on those situated in the interior of organs. The question suggested itself whether the action of the rays in destroying a portion of the leucocytes and irritating the others did not, perhaps, increase the formation and the activity of the body's protective substances. Experiments show that under the effect of the rays there is an increase in the hemolytic cytose, and that animals exhibit a remarkably greater resistance to the action of pathogenic organisms. These experiments are only rudimentary, but they open up an interesting vista for future work.—*Zentralblatt für innere Medizin.*

**Pemphigus Contagiosus Containing Leishman Bodies.**—W. Turner refers to several cases of this nature which came under his notice among the British soldiers at Multan. He states that the sore, on exposure, presents a pinkish, slightly glazed-looking patch, in the earlier stages, but becomes a dirty ashy gray color later on, and is covered by a varying thickness of disintegrated tissue. When this tissue is scraped off gently, it leaves a bleeding surface. He examined these scrapings on prepared slides which were stained by Leishman's method for malaria. He discovered Leischman bodies in great numbers in some cases, and fewer in others. The bodies are oval, sharply defined in outline, with one end rounded and the other pointed. They measure from 2 to 4 $\mu$ in length. Inside the body is a nucleus which stains lilac and occupies from a quarter to sometimes half its size. It is peripheral in position, and may be circular or variable in shape. A smaller chromatin spot which is always circular is near the nucleus, while adjoining the nucleus is a part of the body which does not stain, and beyond this is the stained periphery. These bodies appear to be identical with the Heleosoma tropicum of Wright, which causes the Oriental boil, and so it is thought reasonable to conclude that the "Multan sore" has an origin in the vesicular disease of pemphigus contagiosus. These cases were treated in the following way: The blisters were first removed, the sores scraped, and antiseptics applied. One of the slides was examined by Semple of the Pasteur Institute of India, and he pronounced it to contain Leishman bodies.—*Journal of the Royal Army Medical Corps.*

**Grave Puerperal Anemia.**—Clivio considers 25 cases of severe anemia in puerperal patients, observed by him in the clinic at Parma. He takes into consideration the influence of pregnancy on the woman, and shows how she may pass from a chloroanemia to a pernicious anemia. From these considerations he draws the inference that interruption of pregnancy is necessary in those cases in which blood examinations show a progressive diminution in the number of normal blood corpuscles. In the period of cure of such cases he has observed a marked increase in the size of the spleen, as if the organ reacted to the necessity of destroying the large number of incomplete corpuscles present in the blood. The treatment should be both obstetric and medical—interruption of pregnancy first, then treatment with red bone marrow in the fresh state, and later arsenical preparations.—*La Riforma Medica,* June 3, 1905.

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended July 1, 1905:

### THE AMERICAN MEDICAL ASSOCIATION: ITS ORIGIN, PROGRESS AND PURPOSE.*

By LEWIS S. McMURTRY, A.M., M.D.,

LOUISVILLE, KY.

Both established usage and the by-laws of this Association require the presiding officer to deliver annually an address touching such matters as he may deem of importance. In the early years of the Association the president's address was devoted to an epitome of the progress of medical science in its various departments during the preceding year. Since distinguished orators are now selected annually to perform this important service, the president's address may be more appropriately directed to subjects relating to the general welfare of the profession and to the purposes for which this great organization was established.

The annual session of the American Medical Association is always an occasion of special moment and universal interest to the medical profession of America. That several thousand physicians from all sections of our broad country assemble annually for the advancement of medical science and the elevation of our profession is a splendid testimonial to the earnestness of professional achievement and aspiration. The occasion cannot but command the respect of all who are concerned in the progress of science and the betterment of the human race. The spirit which pervades such an assemblage is the desire for improvement, for the increase of scientific resources, and for the diffusion of medical knowledge. Closely related to these ennobling purposes is that social instinct of our profession, which would elevate and be elevated by interchange of views resulting from common experiences, and by mingling together in pleasant friendly intercourse. Happily our present meeting is held under ideal conditions for the exercise of all the functions of such an organization. Perfect harmony prevails. The differences which at times have divided us, have all been satisfactorily adjusted; and we are to-day as one man in our united effort to advance the science of medicine, to enlarge the scope of its beneficence, and to promote the welfare of our profession.

Since our meeting at Atlantic City one year ago, many of our members have ceased their labors and passed to the great beyond. The list is a long one. Among the number is that of Nathan Smith Davis. He was one of the founders of this Association, an ex-president; a member of the Board of Trustees, the first editor of *The Journal*, and for years a power for good in its affairs. He lived beyond the time allotted by the Psalmist, and all his years were filled with labor and honor. I will not undertake at this time to estimate adequately his great services, or appropriately to pay tribute to his memory. This will be done later in the session by one better prepared than I to eulogize our departed leader.

At our last session, Dr. B. C. Pennington of Atlantic City, was chairman of the Committee of Arrangements. He was honored with the fourth vice-presidency in recognition of his ability, his high professional standing, and his devoted services to this Association. His name, too, is now found among the year's honored dead. A cultured gentleman, a learned and accomplished physician, his memory will ever remain as an inspiration for high ideals and noble endeavor.

When the American Medical Association was organized in 1846 it is doubtful if there were more than 25,000 physicians in the entire United States of America. It was organized as a representative body, composed of delegates from affiliated societies, colleges, and hospitals throughout the states. It was a body of delegates from all state, district, county, and other medical societies which adopted the code of ethics of the national association. The apportionment of delegates was on the basis of one for every ten members of the societies represented. For a number of years the delegate body thus constituted was not too large for the discussion of important subjects and the ready transaction of business.

With the rapid increase in population, the admission of new states to the Union, and the settlement of new territories came a vast increase of physicians, with a corresponding multiplication of state and county societies. Without change in the apportionment of delegates, the national association developed into a body too large and unwieldly for the transaction of business. Indeed, during the latter years under the original system of organization, practically every member in attendance on the annual sessions was a delegate. While the work of the sections was carried on with increasing excellence, the important functions relating to legislative and other matters belonging to a great national organization of the medical profession, were neglected. The general sessions brought together hundreds of delegates, forming a convention so large that thorough discussion of important questions and judicious action on the same became practically impossible. Moreover, the delegates attending the annual sessions constituted a body annually changing in personnel; and the sources of attendance changed with the sections of the country in which the meetings were held. In consequence there could be neither that equal representation of all sections which must obtain in a national body, nor continuation of work from year to year along definite lines.

During these early years it was the steady improvement in the work of the sections which drew the best element of the profession to the annual sessions. Many leaders of the profession in the various states attended the sections in which they were interested, and took no part in the proceedings of the general meetings. The sections have now reached such a high degree of efficiency that they have attained the standard so much desired, and rank as

*President's Address, at the Fifty-sixth Annual Session of the American Medical Association at Portland, Oregon, July 11-14, 1905. From advance proofs by courtesy of the *Journal of the American Medical Association*.

leading special national societies in the several departments of medical science which they represent.

As chairman of the Committee on Sections and Section Work, I have carefully studied the workings of the sections. As a result of this experience, I would repeat the recommendation of my distinguished predecessor in this chair, that the secretary of each section should be elected for a term of years. No national society can maintain its efficiency which changes its secretary annually. And, again, I would suggest that the officers of the several sections meet together in conference as soon as practicable after the adjournment of the session at which they are elected, in order that definite plans may be formulated for the scientific work of the next annual session. The conference of section officers in New York last November contributed much toward the development of the admirable scientific program now before you for the present session.

It should be the aim and purpose of every member of this Association to aid the officers of the sections in elevating continually the standard of scientific work. Every American physician may have pride in the work done year after year in the sections of this Association.

It would be a difficult task were we to undertake a definite estimate of the influence of *The Journal* in the great work which this Association has accomplished during the past two decades. When it was decided to discontinue the annual volume of transactions, and to establish a weekly journal, the change was viewed with apprehension by many. The influence of this publication, the property of the Association, in stimulating research, diffusing knowledge, elevating professional thought and conduct, and building up this great organization cannot be computed. This part of my discourse is so replete with suggestions, that I fear the time and space at my command will not permit such consideration as should be devoted to it.

The volumes of *The Journal* mark the steady and continued growth of the Association, and likewise bear testimony to the fact that *The Journal* itself has been a potent factor in that growth. Under the judicious direction of the Board of Trustees *The Journal* has steadily advanced as a scientific publication. By the untiring daily services of the present able editor, it has leaped into the very front rank of scientific publications, and in all that a great weekly medical journal should be it has no superior in the world. The power exerted by such a publication as a medium of communication among the members of the Association is inestimable, to say nothing of the other more important functions performed by a great weekly journal. It has been the most potent instrument in building up this Association to its present proud position as the largest medical organization in the world. No other American medical periodical has a circulation so distinctly national, and no other journal can sustain the same relation to the great body of the medical profession. It is a great engine whose power is constantly increasing, constantly extending. With such increased power comes increased responsibility, much of which rests with the House of Delegates in the selection of proper men to fill the responsible places of the trustees. No other office should be regarded higher in honor than that of the trustees, as no other affords greater scope for unselfish labor and efficient service to the Association. Under the conditions of our organization more power is invested in this board than the combined power of all other officers.

At the annual session of 1900 a committee on reorganization was appointed, and one year later, at St. Paul, the report of the committee was submitted and adopted. It included a new constitution, which altered the basis of apportionment for delegates, so as to reduce the delegate body to 150, and definitely established a close relationship between the national organization and the state, district, and county societies. For the first time a practical scheme of complete organization of the medical profession of the United States was provided. This is the fourth annual session held under the new plan of organization.

Previous to the reorganization, the valuable scientific work of the sections constituted almost the sum total of the effective work accomplished by the Association. Matters appertaining to medical education, to the public health, to national legislation, and to the welfare of the profession received no deliberate consideration; and in consequence no decisive action was carried out. This condition existed for the reasons already mentioned. In a word, the very objects and aims for which the Association was organized were thwarted by the growth of the Association into an unwieldy delegate body. Under the reorganization the House of Delegates, in which the membership of the state societies is proportionately represented, now gives deliberate consideration to those important matters, already indicated, which under the former organization were neglected.

The influence of the revised plan of organization was immediately apparent in the increased attendance at the annual sessions, and the stimulus felt in every purpose of the Association. And each year this influence has grown, until some idea can now be formed of the great possibilities to come from organization on a definite and practical plan. The good results to accrue to the profession as a whole, and to every member as an individual, are so positive that no subject can deserve more careful consideration by this body than that of medical organization. Indeed, it is the fundamental question before us, and on its decision depend the results of all our other efforts in all directions.

In order that we may thoroughly appreciate the origin and purposes of the Association, and thereby be better prepared to meet its present and future requirements, I have very imperfectly outlined the history of its earlier years. During the more than half century of its existence it has always brought to its councils the ablest and best men in the profession of America. Among its leaders from the beginning are found the most eminent physicians and surgeons of the day. In the list of its active members are the names of Samuel D. Gross, Paul F. Eve, Austin Flint, Marion Sims, N. S. Davis, Alfred Stillé, Lewis A. Sayre, and many others which adorn the annals of American medicine. It has from the beginning been a great power with the profession of America. Its greatest influence, as I have already indicated, was in the growth and diffusion of scientific knowledge through the splendid work of the sections. In elevating medical education, in promoting legislation, and advancing the powers of public health organizations its influence was most felt in the development of a helpful public professional opinion. The extension of the influence and advantage of organization to the masses of the profession was gradually lost sight of in the annual meetings, and the work relating to matters of public policy was spasmodically considered and imperfectly executed. Whatever was accomplished along these lines worthy of mention was the work of the committees. The necessity of reorganization was appreciated by the leading members of the Association long before it was accomplished. In 1888, Dr. N. S. Davis, as chairman of a committee appointed for the purpose, reported a scheme of reorganization very similar to that adopted in 1901 at St. Paul.

"The object of this Association shall be to federate into one compact organization the medical profession of the United States, for the purpose of fostering the growth and diffusion of medical knowledge, of promoting friendly intercourse among American physicians, of safeguarding the material interests of the medical profession, of elevating the standard of medical education, of securing the enactment and enforcement of medical laws, of enlightening and directing public opinion in regard to the broad problems of state medicine, and of representing to the world the practical accomplishments of scientific medicine." (Article II, Constitution of the American Medical Association.)

If every physician worked alone, relied on his own unaided observation for his knowledge, never looking outside his own scope of view, ignorance would prevail, and there would be no progress in medical science. Medicine is not an exact science, and until perfected by extorting from Nature all her secrets, it must from the nature of things continue to be a progressive science. Never before in the history of medicine has such marked progress in all its departments been made as during the present age. Theories have been supplanted by facts; laboratory research and clinical investigation have taken the place of tradition and authoritative opinion. To rely on the accomplishments of the college period is to be left behind in hopeless incompetency. The advance of medical knowledge is to be observed first in our medical societies, and afterward in our scientific medical journals. In the medical societies innovations are subjected to criticism and discussion by those competent to judge the merits of scientific contributions. Moreover, there is a stimulus to study and investigation from association with workers in the same field; and one obtains a broader view of every subject so considered. The physician, more than any other professional man, is isolated by the conditions of his life, and to no profession is the educating influence of society work so essential and invaluable. This same condition of isolation is at the foundation, for the most part, of the jealousies and petty bickerings so prevalent in our profession. These troubles are, as a rule, the result of misunderstandings, and are both prevented and corrected by coming together in a society composed of physicians. The lonely worker in any calling is prone to become narrow, suspicious, and morbid. Our medical societies are the great post-graduate schools of the profession, where knowledge is increased and individual character developed.

But the promotion of scientific investigation, and the diffusion of medical knowledge are not the only objects of organization. Our profession has a most essential and important duty in relation to the public health. Through no other agency can municipal, state, and national health authorities formulate and secure recognition of laws to prevent and control disease. Another duty no less essential is to regulate and to control medical education that the ignorant and unworthy shall not be admitted to the privileges of the profession, thereby preserving the time-honored standard of professional honor and scientific capability. In this age of organization, without it the profession is powerless to secure the enactment of humane sanitary laws, by which alone the people can be protected from preventable diseases. The welfare of the profession, collectively and individually, can only be subserved by organization. Without such organization, our profession, as a body politic, will be without unanimity of sentiment or action in relation to the important scientific, ethical, and social questions which confront us; and consequently without influence politically, socially, or otherwise.

In the declaration of the constitution adopted at St. Paul, which I have just quoted, the American Medical Association has undertaken to place within reach of every reputable medical practitioner in the United States these incalculable advantages of medical organization.

The Committee on Reorganization appointed in 1900 has treated this subject in a masterly manner. After a careful study of the condition of the profession throughout the states with relation to organization, reports have been made to the Association showing the needs of the profession and the extent of the work required. A uniform plan of organization for state and county societies, making the county society the unit of organization, and federating all state societies in the national association in harmonious co-operation, has been prepared by the committee. The able chairman of this committee has with remarkable tact, patience, and good judgment given his personal supervision to this great work in almost every state and territory. In his latest report it is announced that all the states and territories, except three, and including Hawaii and Porto Rico, are now organized on a practically uniform plan, with universal local societies, and coincident membership in them and the state associations as the cardinal feature. To illustrate the magnitude of this work, I mention that, under the stimulus of reorganization after the plan of the committee, the Michigan State Medical Association increased in membership in one year from 452 to about 2,100. Texas increased the membership in the same time from 382 to 2,510, while several states quadrupled their membership. While these results are phenomenal, and elicit our admiration, it will be realized how much remains to be done when it is considered that few of the states have over 50 per cent. of the eligible members of the profession enrolled as members of the society. Indeed, the work is yet almost in its infancy. What has been accomplished is an assurance for the future; and considering the brief time since reorganization began, is a high tribute to the enterprise of the national association and the work of its able and efficient committee. The possibilities of this work are stupendous, and as it proceeds the Association can confidently undertake the great reforms of such incalculable moment to the profession and the public. In his official report to the House of Delegates one year ago, the chairman of the Committee on Organization, after reporting the splendid results of his labors during the year, said:

"The real test of our organization will come in each state when the first outburst of enthusiasm has passed, and county societies, the foundation for everything, are likely to disappear as rapidly as they have been formed, unless their usefulness to the rank and file of the profession can be demonstrated in a very broad way."

In recognition of this fact, it is of the utmost importance that the personal attention so effectively given to this work throughout the states by the chairman of he committee be continued.

When the American Medical Association was founded in May, 1846, the delegates assembled in response to the following preamble and resolutions of the Medical Society of the State of New York:

"WHEREAS, It is believed that a national convention would be conducive to the elevation of the standard of medical education in the United States, and

"WHEREAS, There is no mode of accomplishing so desirable an object without concert of action on the

part of the medical societies, colleges, and institutions of all the states, therefore be it

*"Resolved*, That the Medical Society of the State of New York earnestly recommends a national convention of delegates from medical societies and colleges of the whole union, to convene in the City of New York on the first Tuesday in May, in the year 1846, for the purpose of adopting some concerted action on the subject, set forth in the foregoing preamble."

From this it is apparent that this Association was founded with the avowed and specific purpose of elevating the standard of medical education in this country. This subject has constantly received consideration from the Association throughout the years of its existence; and while no distinct and positive reform marks its action, the perpetual demand for improvement undoubtedly moulded the public sentiment of the profession which ultimately stimulated action on the part of the medical colleges. Since the addresses of my two distinguished predecessors, who immediately preceded me in this chair, were devoted to the consideration of medical education, I shall only make brief allusion to this subject. The several national organizations and the many state boards which are now dealing with this important professional problem invest the changing conditions with peculiar interest. The present is a transition period in the advancement and reform of medical education in America.

The consideration of this subject in the House of Delegates culminated in the establishment, last year, of the Council on Medical Education of the American Medical Association. During the past year the council has taken up its work with exceptional energy and good judgment, and is directing its efforts along most practical lines. The first annual conference was held in Chicago April 20 last. Representatives of many state examining and licensing boards, of the American and Southern Medical College associations, and of the government medical services, attended and participated in the discussions of the papers presented. The plan and scope of the work of the council can be best appreciated by a consideration of this extract from the address of the distinguished chairman of the council, delivered to the conference:

"What we need is co-operation, especially the co-operation between the medical profession, represented by the American Medical Association, and the state and county medical societies, and the state authorities, represented by the state licensing and examining boards. The most important question, therefore, before this conference is, How can the American medical profession and the state licensing bodies cooperate to elevate and control medical education? It is believed that such cooperation is possible. In such cooperation it will be the function of the American Medical Association to represent and possibly mold the opinion of the medical profession, and employ its influence and the influence of the county and state medical societies in obtaining proper medical legislation. In such cooperation it will be the function of the state licensing bodies to protect the interests of the public and the profession by seeing that the medical laws are properly interpreted and enforced, and from their intimate knowledge with the medical acts they can often be of service in securing or modifying medical legislation.

"It is not the purpose of the Council on Medical Education of the American Medical Association to attempt to arrogate to itself any special powers, nor does it desire to either criticise or interfere in any way with any of the agencies which are already in the field. If its creation is to result in good, it must be the means of obtaining cooperation between the medical profession and the medical schools, the colleges of arts, the state examining boards, the government services, and all the factors which are interested in elevating and controlling medical education."

By securing cooperation of the various state and national bodies engaged in this important work, recognizing the varied interests involved in the numerous states of the Union, and fostering an intelligent public sentiment, so essential for every great reform, the influence of the Association will be of the most effective character.

Chapter VII., Section 3, of the by-laws provides a permanent Committee on Medical Legislation "to represent before Congress and elsewhere the wishes of this Association regarding any proposed legislation that in any respect bears on the promotion and preservation of the public health, or on the material or moral welfare of the medical profession." This committee was appointed in 1903, and under the leadership of its accomplished and energetic chairman, proceeded at once to organize the auxiliary committee provided in the by-laws. This being a permanent committee, its work will be continued from year to year. With the auxiliary committee, representing every state in the Union, and the several medical departments of the Government service, every representative of the people in Congress can be reached directly. The importance of this work is so apparent that I need only call attention to it at this time, and urge on all members of the Association the necessity of aiding and co-operating with the committee at all times. The disregard of the good work of the medical profession in the public service (to say nothing of the indignities offered) on the part of Congress is notorious; and it is only by such concentrated power of the profession, intelligently directed, that such injustice may be overcome. I commend to your consideration the report of this committee in order that you may appreciate the important work already projected.

The use of proprietary medicines in the treatment of diseases has become one of the most confusing and demoralizing questions of the day. All proprietary medicines must not be classed as secret nostrums, for there are many honestly made and ethically advertised proprietary preparations that have therapeutic value and that deserve the approval of the medical profession. But there are many preparations offered the profession, which are protected by copyright or trade-mark, with formulæ more or less fictitious, and for which are made extravagant claims, which are, in fact, secret remedies. These preparations are so exploited by the manufacturer that the physician is persuaded to use them instead of writing a prescription; and since they usually bear popular names and plausible therapeutic claims, they appeal to the fancy of the laity. The field is an enticing one for commercial enterprise since these preparations in many instances are simply mixtures and contain the most inexpensive drugs. The use of such remedies is both unscientific and unjust, alike to physician and to patient.

The separation of the legitimate pharmaceutical preparations from the class of fraudulent nostrums described is a most difficult undertaking. This perplexing problem forced itself from year to year on the attention of the Board of Trustees in the effort of the board to keep the advertising pages of *The Journal* free from unethical advertisements. In order to have thorough protection and to make no unjust discrimination, the board has established the Council on Pharmacy and Chemistry to make the necessary investigations. The council is composed

of pharmacists and chemists of national and international reputation. It will be the aim of the council to publish in book form, a list of the preparations which are not officinal, yet which conform to the proper ethical standard. The work of the council will be similar to that of the Committee on Revision of the United States Pharmacopeia.

The magnitude and importance of this work is such that I desire to direct attention to it here, and to commend it to the members of the Association as deserving every possible aid and advancement. It is the only practical way to deliver the profession from one of the greatest curses that ever came on it.

It has been my endeavor on this occasion to outline the plans of the founders of the Association, briefly to trace the evolution of those plans throughout half a century of progress, and to recount some of the purposes that invite our active exertions at the present time. From a small body of delegates our Association has increased until it is now the largest medical organization in the world. It owns valuable property, has accumulated a considerable fund, and has a large annual income, all of which belongs to, and is subject to the control of, the members who through their delegates select the Board of Trustees to manage their funds.

The possibilities of the work before us are almost beyond calculation. In acting as the representative and agent of the 120,000 physicians of the United States, the Association is assuming great responsibilities, which will increase from year to year. It will require administrative and executive ability of the highest order to meet these demands; but there is both prophecy and proof in the work already accomplished that men will appear as needed to discharge the supreme duties of a great profession in behalf of science and humanity.

---

## THE DELAY OF OLD AGE AND THE ALLEVIATION OF SENILITY.*

By CHARLES G. STOCKTON, M.D.,

BUFFALO, N. Y.

In 1805, Lewis and Clark, typical and celebrated among American explorers, turned their faces toward the furthest west and disclosed in a single expedition the possibilities of the continent and the mysteries of the great undiscovered. Their feat was in principle but a repetition of the undertakings of Columbus, De Soto, and La Salle, of Daniel Boone and the numberless pioneers who so quickly, almost suddenly, transformed America from a desolate wilderness into the puissant commonwealth of today. In each we may discern a discontent with the established order and environment of his heritage; an inspiration to find in newness a satisfaction which the settled regions, settled habits of thought, settled manners of life failed to provide him at home. The word "settled" is significant. Our race is without rest until it settles things; and with this there stalks a poignant impatience with the things that are settled. The new, the undiscovered, the unattained, the unprecedented, this it is which causes American manhood. The Muezzin calling his prayers from a minaret in far away Cairo, the yellow haze in the circumambient air, the camels with jingling bells, the palms turned always eastward by the hot breeze from the monotonous sands—these possess for the western man no attraction greater than that of poetic interest. In these scenes he could never make his life.

*Oration on Medicine at the fifty-sixth annual session of the American Medical Association at Portland, Oregon, July 11-14, 1905. From advance proofs by courtesy of the *Journal of the American Medical Association.*

The European finds in America everywhere that which impresses him with our youth; in the Orient, he sees the indisputable evidence of age and a settled order of things. This exploitation of new lands, the cry of "Westward Ho!" which for the past few centuries has stirred mankind, is rapidly, inevitably dying out; but during the long period of its continuance it has wrought important changes in our point of view, it has stimulated a luxuriant growth of thought, it has modified considerably our nature. As our common interest has been fixed upon the untried, we have gradually come to exaggerate the importance of new truths and to ignore the meritorious which the slow-moving caravan of thought has brought us from ages.

Now, it may seem a *non sequitur,* but reflection leads one to inquire if the great appreciation which we feel for the vigorous youth-spirit of recent times, has not educated us to prize, perhaps to over-value, youth, to the disparagement, if not to the absolute neglect, of old age.

In saying this we are not unmindful of the element of truth in the rightly interpreted utterance on this subject of one of our most distinguished colleagues. From the standpoint of the original investigator, as from that of the soldier, or the adventurer, there is nothing to replace the effort of the man under forty; but if for no other reason than to obstruct impetuosity and to provide such a handicap that youth shall not too soon outrun the limitations which a wise Providence has provided, middle and late old age have their uses. At any rate the old man is with us and there appears to be no acceptable method of obliterating him, even if it would add to the welfare of the race to do so.

Finding ourselves in this obvious position, it would seem the wise course so to manage that the disheartening effects of years may be as long as possible postponed; and to seek those methods by whose application we may do our utmost to minimize the terrors of senility. If youth is so delectable, let us find how it may be protracted; if old age is so beset with ineptitude, let us not rest until we learn how it may be mitigated. Such a proposal is not quite identical with a scheme for the prolongation of life—mere increase in years, although it would doubtless include this, however desirable or regrettable it might be. It has to do directly with something about whose desirability there can be no doubt. In other words, I ask your attention to the question of the practicability of *keeping* the various functions of the organism, of preserving the physical and intellectual powers, of delaying the onset of degeneration as much as may be, of developing a race less prone to early decay.

Then, besides this, I wish you to consider the feasibility of so managing the senile when once their degeneration has arrived, that many of their miseries may be avoided and the remainder lessened in degree. Having granted that age is inevitable the average man would seem to have become indifferent to his penalty for living, and, if complainingly, he none the less heedlessly allows his forces to ebb away prematurely. With some the whole of existence seems to be spent in infancy, adolescence, and senility. There is no period in which one can say, "there is full, healthy maturity." When examined this early senility is found to result from pathological processes and there the observation ends as though it were conclusive. But the event is not thus to be disposed of, for, according to our best standards, senile changes are always pathological, and, therefore, the question of prematurity rests on some pathological reason for cause, or else upon inherent weakness in human vitality. We are in the

habit of speaking and thinking of senility as something separate and apart from disease; as a result, not sufficient attention has been given to the question of prevention of age.

On this subject one cannot escape the bold work and bolder thought of Metchnikoff, and I quote at once his description of the degenerations of age. "In senile atrophy the same condition is always present: the atrophy of the higher and specific cells of the tissue and their replacement by hypertrophied connective tissue." It is this same process on which every teacher of medicine constantly harps in discussing disease, the disappearance of the parenchyma and the increase of the stroma.

One need not dwell on the theory of Metchnikoff as to the *rôle* of the phagocytes in the process; for the moment it is enough to know and to recognize that senile atrophy is pathological and that, essentially, old age is disease. It is unnecessary to discuss the plausible but startling suggestion—that of finding some antiserum which might antagonize the development of the age producing agencies. Already we possess some knowledge of how to defer age, but this information is not generally insisted on as a guide in living. We frequently allude to measures of prevention, but we do not reduce them to a system which can be taught to the student and to society. If we are further to lengthen the probational study period in medicine, it will be wise to give the matter of deferred old age very careful consideration. If the subject were studied seriously, we would foresee a tremendous improvement in the type of humanity, and the readjustment of many habits, customs, social questions along altogether new lines.

Obviously, real progress cannot be made without accumulating data from which to deduce positive conclusions. At present we lack information on such simple matters as the effects on the organism of diet, exercise, recreation, and rest. There are many opinions, but they are largely theoretical. To begin with, we must know something about the material with which we have to deal; that is, the inheritance, the reserve powers, the internal resistance of the individual. In fact, we know very little concerning the inheritance of any one. All are more or less obscure in the matter of family history. There are courts of record in which are found descriptions of estates, but there are no archives in which are deposited accurate descriptions of the various members of the family itself. We are more particular in relation to our domestic animals, especially in the introduction of a new strain. Inquiries are made as to the matter of endurance, longevity, powers of nutrition, good or bad qualities of mind or body, but concerning ourselves there is an indifference to these important qualities of organic perfection. It would not seem to be altogether impossible to acquire some official record of the physical and intellectual qualities, in other words, strains in men. It is not improbable that if such records were known to exist, they would be not only consulted, but would gradually grow to have an influence on the formation of families. Love is said to know no barriers, but history fails to confirm this view. If a matter of class, of caste, or rank, has been sufficiently important to control the forming of marriage contracts, it is not impossible to conceive of a more intelligent public sentiment which would make an alliance with a family celebrated for physical, intellectual, and moral superiority, a thing greatly to be desired; and conversely, which would lead to the abhorrence of an alliance with a family in which freaks, degenerates, and incompetents, or in which a tendency towards lowered nutrition, too early maturity, or premature senility were frequent events.

Naturally this is not an affair of a generation, but it is unquestionably a doctrine which ought to be taught. The notion that acquired characteristics can have any transmitted influence on the character of the offspring, as formerly taught by the Lamarckians, is still doing great harm. Our young people should be instructed in the fact that the well being of their posterity depends almost altogether on the native stamina of the germ-plasm with which they are endowed. They should be taught to understand the responsibility implied in maternity and paternity, and should be made to recognize that the greatest influence which they can have on the well-being of their children is in the selection of the spouse. The sentiment should be encouraged that parentage is a matter which concerns the public, and especially posterity, more than it does the parent; that the germ-plasm of the race is of all questions the most important which concerns it. Measures could be adopted which would make it more possible than at present for individuals to inform themselves concerning the family characteristics of the contemplated fiancée. A bureau for the precise registration of disease and causes of death, together with the chief facts in family and personal history, might be established through legal enactments, reinforced and made active by a high social sentiment. Such a bureau would afford the needed information, and the special study of the material thus provided would result in the formation of guiding principles in human biology and race development.

Such a system might seem to be contrary to our laws of personal rights, and, of course, the sanctity of reserve may not be easily disrupted. Nevertheless, with Emerson, "We shall one day see that the most private is the most public energy; that quality atones for quantity," and, although we cannot attain at a bound to these heights of wisdom, we may, at least, begin to map out a way. He is short sighted who supposes that the complacency shown in the devolution of the race must continue, unchanged, eternally. We have only admiring applause for the remarkable accomplishment of Burbank in the vegetable world, and yet such are our deep-rooted prejudices that we shrink from the application of similar principles to human uplifting even when we know it is possible. Shaler remarks that man "sorely needs a herdsman's care." The subject is painful, yet I think it will be acknowledged that susceptibility toward tuberculosis, insanity, alcoholism, epilepsy, *et cetera*, is hereditary. Granting this, it follows that a stock could be developed which practically would be immune to those diseases. Doubtless all will regard the realization of this suggestion to be remote and some may liken it to that of Maeterlinck, who says: "Man may some time master the secret of gravitation and by means of it steer his planet wherever in the universe he wills." The principle is open to such wide application that it may easily be obscured in absurdity. Nevertheless, here is an honest, straightforward truth not so far beyond our reach. It lies in a public demand that none but healthy parents shall be allowed to bear children. The brevity of middle age resides, first, in the inherited quality of the organized tissue; second, in the effects of its environal conditions on each organism. We physicians are making it our function to exterminate disease. Why should we be content with merely pointing out that certain disease tendencies are hereditary without taking some practical steps to prevent such disease transmissions? As an illustration, it doubtless would be a hardship to the syphilite to make procreation for him a penal offense. Nevertheless, such a course would be full of beneficence to the race. The amount of nervous and other disease

in the innocent resulting from syphilis in progenitors is incalculable. The incompetence and misery which often overtake the unfortunate victim in middle life as the result of syphilis, one or two generations removed, must be considered. Those who have studied the subject carefully, regard this disease as responsible for one-fifth of all cases of arteriosclerosis, and yet higher proportion of those cases occurring in middle life. A man has not the moral right to beget disease. Notwithstanding that it usually comes through ignorance, it should not be allowed. The profession of medicine should make its convictions bear fruit, and should teach, and should be expected to teach, that the marriage of a large number of people whose nuptials they now help to celebrate, should either be prohibited or else made barren. To those who would regard the realization of these thoughts as unattainable, it may be remarked that the world is yet very young, and as a result, as Carlisle has said, in most things very stupid. At any rate it will be admitted that middle age could be considerably prolonged and the infirmities of old age largely mitigated if we could eliminate from the equation that faulty cell metabolism which arrives through inheritance.

The trend of modern thought is toward the development of the individual. Our researches in therapeutics, dietetics, immunity, gymnastics all alike are directed toward the betterment of the individual by making life possible to many who would otherwise perish, comfortable to many who would otherwise survive in misery—results in prolonging life. Our educational efforts concern themselves more and more with fitting for life the otherwise unfit, in so dealing with the neurotic, the semi-imbecile, the vicious and criminal that they may be practicable units in the body politic. The result is that individuals otherwise impossible are so modified that they are finding some happiness in life and become less disturbing elements in society as a whole. There can be no doubt as to the benefit to the individual and no doubt as to the good which comes from the reflex effect on society. Perhaps nothing counts more for the moral uplifting of the masses than the awakening of personal interest in all altruistic undertakings, but let me repeat, we must dismiss as untenable the views of the Neo-Lamarckians that acquired characteristics of the individual have any appreciable effect on the offspring. It is acknowledged that the natural tendency of defectives of all kinds is toward extermination. Left to themselves, many of these weak strains would disappear. In making it possible for these strains to continue to blend and to dilute the organic type of the race, we are unquestionably lowering the future standard of internal resistance and we are creating a threat to physical, intellectual, and moral perfection.

On this subject Professor Woods Hutchinson, of this city, has said some interesting things.

Is it unchristian or unethical to consider this question from the phylogenic standpoint, or, on the contrary, is it not from the highest ethical plane that we look forward to a means that may elevate man spiritually, strengthen him intellectually, increase his vital and physical vigor, thus widening the period of his usefulness and decreasing his sufferings as a whole? We find ourselves sustained in our efforts when they are directed toward helping the individual, but there seems to be a social veto placed on the study of generic betterment. Weismann and his followers have shown us that the character of the individual depends on the germ-plasm with which he starts life, and although education and favorable environments may modify greatly the individual, the values have no effect whatever in improving the character of his posterity. The possibilities of an individual, his resistance to disease, his longevity, his strength, and his intelligence are determined beforehand by his inheritance. It is known that it is possible to bring deterioration by introducing an inferior strain. No educational advancement can counteract the injurious effects of this preservation and inbreeding of the bad stock. Unless intelligent foresight be used to prevent this definite and ascertained source of degeneracy, we are likely to find a growing depreciation of our racial stock and, in spite of our modern preventive medicine, a progressive increase of mental and physical disease, and an abbreviation of the working years. By homely methods we have learned that aside from the question of perfect nutrition and proper exercise of function, there is nothing which contributes so unquestionably toward the improvement of organic life as intelligent study of what is known as breeding, in other words, by the intelligent blending of the germ-plasm of healthy, resisting, long-lived stock, so that there may result not inferior progeny, but offspring superior to the parental stock. I am aware that the question is not new, and that its mere mention exposes one to criticism, not only from the timid and ignorant, but even from the wise and philanthropic; and yet, no one can deny that in shutting our eyes to this truth which Nature spreads plainly before us and which she makes the subject of countless lessons illustrated by individual inferiority, perversity, disease, and death, we are not doing all that we ought for the coming race, not all that we might toward assisting that evolution which we hope for, but which lingers so in the process. It will be said that no one can contemplate such a scheme as is here suggested without feeling strongly convinced of its impracticability. Of course, it must be admitted that the large fulfilment of such ideals is at present quite impracticable, but it is not impracticable to study the subject with the hope of finding certain aspects which may admit of modification.

By a study of the subject we would at least offer a reasonable antidote to the possible injurious effects of the modern rage for individualism. More than this, it may be possible, by more or less united action, so to modify established customs, social tendencies and common law that we may elevate the sense of family, and possibly municipal and national morality to a standard high enough to result in our placing the welfare of the community above the desires and the instinct of the individual. As we have somewhat meddlesomely diverted the natural tendency of deterioration and degeneration from its end, thus interfering with the action of the law of the survival of the fittest, it does not seem improper that individualism should recompense society by yielding some of its prerogatives for the welfare of the race; or, to put it more pointedly, it would seem only fair, since we have preserved the life of the weakling, that we should deny him the privilege of paternity, or since we have educated the defective or criminal youth into semi-useful citizenship that we should forbid him the right of increasing the number of his kind. In one of our states a legislative enactment looking toward this end was recently vetoed by the governor, who accompanied his decision by a conventional lecture to the profession of medicine on its willingness to disregard the rights of individuals. This illustrates one of the difficulties in the way, and would seem to indicate still another field in which physicians must assume their rôle of public educators. The sentiment of the people is instinctively against public interference with personal privilege. This feeling seems to be particularly strong in the Anglo-Saxon people, and to be contrary to the nature of our institutions;

yet, like every other privilege, it is susceptible of doing great evil if carried to its full logical extreme.

Are we not as an organic type suffering from an extreme application of individual rights? Are we not inflicting an injury on the race through permitting unwholesome privileges to the individual? Is it necessarily dangerous to attempt to create a public sentiment, a social feeling, toward the making of new customs and the enactment of new laws which may result in the elimination of at least some of the more abhorrent and destructive elements that at present are blending with and antagonizing the evolution of the race? Would it not be desirable to have an aristocracy of health? That is to say, to see developed a zeal for physical and intellectual perfection, and to have that zeal supported by public sentiment, so that there might be created something like a caste, the attributes of which should be mental and physical wholesomeness, and from which should be excluded those families which are shown by carefully studied data to come of degenerate or unfit stock? This would result in a contest between the general and the particular. At present the particular, the individual, prevails; in the presence of rightly adapted social feeling the general would prevail. Evolution would thereby be speeded and not retarded as at present. The principle involved does not seem to be any more unethical than the application of the quarantine laws which now operate injuriously to the individual, but make greatly for the public good.

Let us now consider what may be accomplished in the way of postponing age by the reasonable treatment of even the poor material that comes to us. Undoubtedly the question is as broad as the whole subject of personal hygiene and general therapeutics, and so, for the most part, must be passed; there are, however, some aspects of the subject which deserve special consideration. One of these is the improvement in the nutrition of the aged as the result of good teeth. While all recognize the comfort and convenience which we owe to the dentists, it is doubtful if we fully appreciate how much they have contributed to good health and longevity. For another great advance we have to thank the oculists. Who can estimate the additional resources both of usefulness and happiness secured through the discovery of spectacles and the operation for cataract? Useful eyesight contributes much toward health and long life for the reason that it permits of a continued interest in living which otherwise would be lost. It permits of a struggle for an ideal and in this real happiness consists. The ideal, of course, is never reached, but, as Montaigne says, the reward is not found in the victory, but in the conflict. Perhaps no one factor is so important in maintaining courage and health in old people as the creation and continuance of some keen interest in life, and this interest, even in the otherwise enfeebled, may be kept up by means of useful eyes.

Now comes the timeworn but neglected subject of arterial disease. Too often our attention is for the first time attracted to arteriosclerosis by the appearance of fibroid or fatty degeneration, exhibiting itself in the figure, form, and viscera of the individual. Even after these later changes appear measures may be adopted to stay the march of the process, but how much better it would be to anticipate it. For instance, by noting the high and rising blood pressure and the physical signs of cardiac strain, by estimating the decline in urinary solids and the rise in the urotoxic unit, by measuring the decline in respiratory capacity, or by detecting the falling off in cutaneous secretion and the loss of the pliability and softness of the skin, we may make ourselves aware that vascular degeneration is progressing. Heedless of these earlier manifestations we shall soon awake to the advent of the state which Sir James Paget has so marvelously described.

In the earlier steps of arteriosclerosis, if intelligent study be given to the individual, to his habits of life, to his excesses, and to his deficiencies, very much can be done, and, by thoughtful men, is done, to delay arterial changes and to restore functional activity.

May I trespass so far as to emphasize the importance of judging and correcting the disturbed balance between assimilation and waste—the anabolic and katabolic processes? The facts are so well understood that one hesitates to mention them, and yet just here there is so much neglect of precious opportunity. There are successful methods of lessening the extent of autointoxication and of widening the field for the play of nutritional processes. This is so commonplace that we neglect it. Middle age often brings luxury and at the same period the contracting arteries narrow the field of physiological activities. The circumstances of life and the taste of the man are for indulgence in appetite or for excess in undertakings, while the limitations of the organism are increased. The tendencies are thus in opposite directions and, with Munsterberg we ask, "How can they keep together who are going different ways?" Ultimately, they must separate, of course, but temporarily they may keep company if we help to preserve harmony between them. There is abundant proof that even advanced arteriosclerosis may be so far modified as to delay the oncoming degeneration and to admit of happy usefulness, but the victim must be content with moderation and not hope, like Mahomet, to cleave the moon in twain.

Advanced arteriosclerosis is too generally neglected, and intoxications, of one kind or another, are for the most part responsible for it. Our prophylactic and curative measures are readily understood. It is well known that the relatively great fatality of pneumonia and other acute diseases is explained by the greater toxemia which exists late in life. Besides this, the autointoxication increases the blood pressure and induces prematurely the fatal events of cerebral, cardiac, and renal diseases. Almost as deplorable as these are the conditions of unnatural excitement, confusion, and depression from which many people unnecessarily suffer in early old age. Still further there may be found in vascular disease the source of much severe pain from which old people suffer. This pain is often referable to the aorta, at times to those forms of aortitis which Clifford Allbutt has described, and also to aortitis and periaortitis of the abdomen recently so well set forth by Teissier of Lyons. The latter has also shown that the pain can be ameliorated, the progress of the disease stayed, and even great improvement induced by rational treatment. Aortitis and periaortitis often greatly interfere with the flow of blood into the branches of the abdominal aorta, and as a result the organs supplied by these branches suffer special degeneration. In middle age and later life, intractable diseases of the stomach, intestines, kidneys, and other organs could be dealt with much more successfully, and comfortable longevity secured, if more attention were devoted to this pathology.

There remains for brief consideration the question of what can be done to make old age more tolerable; in other words, to remove it to a physiological basis. We find on close consideration that most of the derangements from which the aged suffer can be classified as belonging distinctly to pathology, but I am afraid there exists a tendency among us to dismiss these matters as necessary corollaries of senility,

without giving them that careful consideration which similar processes receive in younger patients. To a few the diseases of old age have a peculiar charm, and these few who give senile diseases special study seem to agree that the complaints of the aged arise for the most part from toxic causes. Even the threadbare question of arteriosclerosis falls to a large extent under this head. There is good reason for believing that this toxic state which underlies the decadence of senility takes its origin for the most part in the colon. Metchnikoff supports the view that mammals have developed a large colon for the purpose of storing the products of digestion, and that man has inherited an enormous colon at the expense of his longevity. This organ harbors an immense number of bacteria leading to fermentations, putrefactions and the production of alkaloids, fatty acids, and toxins, which man has to combat for the length of his mortal days. While vitality is young and vigorous, the combat is not so unequal, but with failing powers autointoxication prevails in the contest between the internal resisting powers of the organism and the toxic adversary made potent by inheritance. Unfortunately the degeneration of age first produces functional insufficiency of the organs of elimination, then their degeneration, and as a result we find the skin, kidneys, lungs, liver incompetent in each individual overtaken by years. It is somewhat remarkable that facts so well understood as these do not receive more attention.

There are few text-books, there is little teaching devoted to the pathology and right management of senile disease, and yet experience teaches that few patients respond more satisfactorily than do the aged if their cases are approached with the principles in mind which are here set forth. It is not merely a question of dilatation of the colon, nor of any special defect of the organ; even in the absence of these, the source of autointoxication exists and becomes important because of the failure of the skin and other emunctories which, earlier in life, are relatively sufficient. The indications are obvious. In addition to the usual measures for improving the general circulation, old people are benefited by systematic colonic lavage, stimulating baths with superficial massage, prescribed pulmonary gymnastics, and an abundant drinking of pure water. It is the almost universal neglect of these matters which has made it seem to me a subject of sufficient importance to call to your attention in a general address. There is something inspiring about youth which gives an incentive to our care of the diseases of childhood and adolescence, but there is something benignant in studying the problems that lead to the postponement of age and to the alleviation of the trials of senility. Old age is repulsive when it is pathological, but is beautiful when it is physiological, and it would appear as a fitting theme for the consideration of this great body at its meeting in this new land of the setting sun.

---

**The Question of Dilatation of the Cervix.**—De Seigneux says that in spite of what has been alleged against Bossi's method, it is founded upon a sound principle, and most of its disadvantages depend on the fact that Bossi's instrument is still imperfect, as are also the various improvements on it that have been devised by others. He himself has invented a dilator quite different in form from the preceding models and which he thinks will obviate their disadvantages. The points he claims for it are that it effects dilatation in the plane of the cervical entrance, and is, therefore, less apt to produce tears; that as dilatation progresses wider tips may be fitted to the instrument; the instrument may be easily taken apart and cleaned; no assistance is needed in using it.—*Zentralblatt für Gynäkologie.*

## CONGENITAL ABSENCE OF TIBIA: TRANSPLANTATION OF THE HEAD OF THE FIBULA: ARTHRODESIS AT THE ANKLE JOINT.*

By T. HALSTED MYERS, M.D.,
NEW YORK.
ATTENDING ORTHOPEDIC SURGEON TO ST. LUKE'S HOSPITAL AND THE NEW YORK FOUNDLING HOSPITAL; CONSULTING SURGEON TO THE NEW YORK ORTHOPEDIC HOSPITAL.

A BOY, 2 years of age, was referred to my service at St. Luke's Hospital, May 5, 1904, on account of a deformity and shortening of his right leg, and his inability to walk.

There had been no deformities in either branch of the family, and there was no history of injury or disease in the early months of pregnancy.

Examination showed the boy to be in excellent general health and perfectly developed, except in the right lower extremity. Measuring from the ant. sup. spine of ilium to the tip of the external malleolus this was 2¾ inches shorter than the left. The femur was normal in shape, but slightly atrophied in all dimensions. The tibia was entirely absent. The head of the fibula articulated loosely with the upper and posterior part of the external condyle of the femur. The shaft was curved outward and 1¾ inches shorter than the left. The foot was in marked equinovarus, being rotated on transverse axis of ankle at 135°, on anteroposterior axis 30°, and on vertical axis 45°. The leg was habitually a little flexed and adducted, with very slight power of flexion or extension, but passively the joint could be fully flexed, hyperextended 15°, rotated in 100°, and rotated out 150°, adducted 10° and abducted 60.° It was so relaxed, therefore, as to be useless for walking, and the child had always gone about on his knees.

Fig. 1.

An examination of the accompanying skiagraph (Fig. 1) will show the absence of the entire tibia, the shortening and curvature of the fibula) and its relations to the femur and astragalus.

The previous treatment had consisted of the application of several plaster splints and a tenotomy of the tendo achillis.

*Read at the annual meeting of the American Orthopedic Association, June 6-8, 1905.

The condition of the muscles was examined for me by Dr. Capito at St. Luke's Hospital, and groups of flexors and extensors of the thigh, leg, and foot reacted normally, though it was impossible to pick out individual muscles. There were none showing reaction of degeneration, which led me to hope that

Fig. 2.

if I could secure use of the limb, its development would be increased correspondingly.

June 21, 1904. Under gas-ether anesthesia, an Esmarch bandage having been applied, I made an incision across the outer half of the joint, below the patellæ, opening the articulation between the head of the fibula and the external condyle, which was lined with synovial membrane communicating with the synovial pouch below the femoral condyles. The latter, much smaller than normal, was in normal relation to the femur, but had only a connective tissue base below where the semilunar cartilages and tibia exist normally. There was a rudimentary crucial ligament rising from this base in front and attached to the posterior and inner part of the outer condyle of the femur. The posterior crucial ligament was not identified. There were two thin, rudimentary patellæ, almost round, of half an inch diameter each, lying, tandem-like, one above the other in the quadriceps extensor tendon about one-third of an inch apart. The ligamentum patellæ, thin and long, running outward and downward, was inserted well below the head of the fibula on its inner side.

The capsular ligament was very thick and strong, and the external lateral ligament was especially so, and had to be freely divided and very considerable force used before the head of the fibula could be drawn down and inwards to a position between the condyles. The patellar ligament was shortened and transplanted to the anterior surface of the fibula; some of the capsule on the inner side was removed and the remainder attached to the periosteum of the head of the fibula in order to hold it more firmly in its new position. The incision was then closed. Rubber tissue drainage was used, as the manipulations had been considerable. Sterile dressing. The objects of this operation were to lengthen the limb (about ¾ inch was gained) without destroying any bone and so interfering with its growth; to secure a sufficiently stable support for the body weight; and to preserve the mobility of the joint in the hope that a useful amount of voluntary motion would be gained with the increase of muscular power encouraged by the use of the joint.

The ankle joint was then opened by a transverse incision, section of the tendons and nerves being avoided, the external malleolus was then cut off and the superior articulating surface of the astragalus denuded. The fibula was then placed squarely on the astragalus and united to it by several strong catgut sutures, the foot being allowed to remain in 45° of equinus. Wound closed without drainage. Sterile dressing. The objects of this operation were to increase the length of the limb, to correct the deformity and to secure a stable position of the foot.

A plaster of Paris spica was then applied, correcting the varus and holding the fully-extended leg in slight knock-knee position to prevent redisplacement outwards of the head of the fibula.

There was considerable pain and reaction after these operations, but by means of repeated leucocyte and differential blood counts we were able to be sure there was no infection of the wounds and the troublesome and painful re-dressing was avoided. These examinations of the blood have often been of great value to me in this way.

Fig. 3.

After two months the child was allowed to walk in this long spica splint.

December 16, 1904. A walking brace replaced the spica. This had joints at hip, knee, and ankle. The pelvic band had perineal straps to relieve the

limb of as much of the weight of the body as was thought necessary. The knee joint of the brace was placed well behind that of the limb, to increase the stability, since the extensor muscles were so weak, and a knee cap was added for the same reason. A cork sole of 1¾ inches equalized the length of the limb.

An examination of the accompanying skiagraph (Fig. 3) will show the position of the bones at the knee and ankle on February 21, 1905. The head of the fibula seems quite firmly embedded in its new position and the amount of motion allowed at knee is from 180° (full extension) to 110° in flexion, no adduction, abduction 40°, rotation inwards and outwards, 20°. The foot is plantar flexed 50°, and the toes have a tendency to rotate on vertical axis into 25° of varus. This is easily corrected by the shoe. The flexor long, polices was divided January 7, to allow full extension of this toe, upon which much of the weight is borne. The perineal straps of the walking brace were discarded after about a month, as the new joints seemed able to bear the body weight with the lateral support only.

The boy can now (June 13, 1905) flex his leg 90° and almost fully extend it. His power is increasing rapidly, and he now walks about all day, as shown in the photograph. (Fig. 2.)

Absence of the tibia is the rarest of the congenital defects, and in a review of the literature I have found but 46 cases of entire or partial absence of this bone. A number of these have been fetus or very young children at death (7, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25) and many have been dissected. In the older children this deformity has been regarded as an almost hopeless condition from the mechanical standpoint, though some surgeons have recommended this form of treatment (15, 26, 27). Usually amputation has been done on account of the great instability of the joints, and the shortening which probably will be progressive (28, 29, 30, 31, 37, 38). I shall give references to all cases I have been able to find, but shall go into details in only those six which were subjected to operations similar to that in my case. I shall, however, give some general statistics, using the article of Joachimstal freely, but carrying them down to date. In very few instances has any serious attempt been made to preserve the leg in these cases.

Albert,[1] in a girl 9 years of age, with a similar deformity to that in my case, first transplanted the head of the fibula to a position between the femoral condyles, as he thought no orthopedic apparatus could be of use, especially on account of the deformity at the ankle. He, however, shaped the head of the fibula to the form of a wedge, and made a corresponding notch between the condyles, and then held the bones in place by a silver wire suture. He secured bony union in slight flexion at the knee. No report is made of the treatment of the equinovarus or of the ultimate result as to function.

Helfreich,[2] in a boy of 1½ years, with absence of tibia excepting a rudimentary head, and marked contracture of posterior soft parts at knee, divided the tendons of the semimembranosus and tendinosus and posterior capsular wall. He could then only secure extension of 135°. He freed rudiment of tibia from head of fibula, which he cut into shape of pyramid and implanted between condyles, securing it there with silver wire sutures. This case was published eight days after operation, and I can find no report of the ultimate result.

Parona[3] reported a very interesting result in a child 20 months old who had defects of all four extremities. The femora were both short, but otherwise normal. On the right there was no patella; the lower half of tibia was absent; the fibula head articulated, as in my case, with the outer side of the external condyle of the femur. On the left side, only the upper third of the tibia was absent; the leg was strongly flexed, and the fibula was articulated with the external surface of external condyle of femur. On each foot were eight toes. A slight varus existed on both sides.

Parona resected the right, and, twenty days later, the left, lower end of femur and the head of fibula, adjusted the bones and secured the straight position thus gained by a water glass splint which was later replaced by steel splints. Ankylosis did not follow, and the child could move the limbs to some extent in flexion and extension, while lateral motion was prevented by the apparatus. The functional result was very good. The child could go alone all day by himself. Parona also thought he observed after some weeks an ossification of the fibrous bands representing the deficient tibiæ beginning to occur under the stimulation of use.

Motta[5] operated upon a boy seven months of age. The femur was 2 cm. shorter than the normal. The patella was present. The tibia was absent. The foot was in extreme varus position and had but three metatarsal bones and three toes. Extension of the leg, which was flexed at 90°, was impossible.

Motta divided the tendo-achillis and then opened the knee joint by transverse incision. The crucial ligaments were absent; the intercondylar notch poorly developed; the lig. patellæ thin and long. The head of the fibula lay behind and to the inner side of the external condyle 4 cm. above its lower surface. To avoid removal of the considerable amount of bone which would be necessary in order to implant fibula between the condyles, Motta made a hollow in the external condyle itself to receive the wedge-shaped head of this bone, and secured it there with a catgut suture. The leg could not be extended. After six months, the boy, with 30° motion at the knee began to make the first attempts at walking with the aid of a splint holding the foot in plantar flexion to increase the length of the limb which was 4 cm. short. There is no later report.

Busachi,[6] in a child ten months of age, found a total deficiency of right tibia; dislocation of head of fibula to the outer and posterior part of external condyle of femur and marked talipes equinovarus. He divided the tendo achillis and corrected the position of the foot. By a transverse incision he opened the knee joint, finding the crucial ligaments and semilunar cartilages absent. He divided the bands holding head of fibula to the external condyle, and implanted it, after freshening it, in a wedge-shaped depression which he made between the condyles. He secured bony union, but also applied a splint to hold leg fully extended, so that the child could stand upon it. There is no later report on the result.

Joachimstal[7] reports the following case: Girl 14 months old. The right leg was strongly flexed and adducted, the foot in marked varus. The femur was shorter than the left. Fibula articulated with posterior part of outer condyle and was 2.5 cm. shorter than the left. The angle of greatest extension at the knee, even with use of considerable force, was 90°. Wolff planned to implant fibula between condyles after overcoming flexion at knee and the deformity of the foot.

Tenotomy of the leg flexors was useless. The knee was opened transversely, the fibula freed from its abnormal attachments and placed between the condyles, and the capsule sewed over it. No crucial ligaments or cartilages were found. Tenotomy of tendo-achillis, correction of deformity of foot. Gradual correction of knee flexion by repeated plaster of Paris

splints. Ten months after the operation the child walked with high shoe, but a plaster splint extending from ankle to hip was worn to prevent relapse of head of fibula, though it semed quite firm in its new position.

The etiology of these conditions has been a matter of endless theorizing, and the arguments advanced by Sperling[8] in reference to defects of the fibula and so-called intrauterine fractures of fibula or tibia may be applied to defects of the tibia. These are epitomized by Cotton and Chute,[9] and I briefly state some of them. A fracture in utero by direct or indirect violence would only be produced with difficulty, the fetus being suspended in amniotic fluid and protected by uterine and abdominal walls. Violence sufficient to cause such a fracture would produce miscarriage. If uterine pressure were the cause of fracture, we should have fractures occurring with some frequency intrapartum, when the intrauterine pressure is greatest. In fact, however, such intrapartum fractures only occur at or near full term, and as a result not of intrauterine pressure alone, but of the counter pressure of the bony pelvis as well. Callus is practically never found in these cases. The presence of the so-called scar is not valuable evidence of a compound fracture. It has even been proven not to be true scar tissue.[10] To these slightly depressed cicatricial spots a piece of amnion is sometimes found attached. This would seem to indicate a small amniotic sac with adhesions or amniotic bands.[13]

The defects of fibula and toes so frequently associated with tibial bends, point to an origin as early as the second month of fetal life, for at this time the parts are laid down and defects in the true sense cannot arise later. These defects cannot be either the cause or the result of the so-called fracture. Hence the association points to a common cause for both. It seems likely that both are due to an abnormally small amnion and its adhesions, the more likely as these seem the cause of other similar deformities. This hypothesis has also been elaborated carefully by Lanois and Kuss,[24] and would seem to the writer to explain well most of the deficiencies and flexions, but leaves unexplained the presence of supernumerary parts and synostoses. These must be due to an abnormality in the arrangement of the original germ cell mass. If this assumption is necessary to explain some of the deformities, it certainly would explain more naturally than the pressure theory certain of the deficiencies, and the variations of the deformities. In one case, for instance, the tibia is absent, also some of the toes; in another, the tibia is absent and the foot is perfect. Albinism has been cited as an example of the possibility of the omission of one element of the normal tissues without interfering with the general development of the body in other respects.[40]

In the 46 cases I have been able to find recorded, the deficiency of the tibia was total 43 times (in 34 subjects), and partial 22 times. In 21 of the latter the lower part of the tibia was deficient. The right tibia was usually absent (39 to 23). The deformity was usually unilateral (31 to 17), and the males were generally affected (25 to 13). In more than half the cases (35 in 46) there were other deformities, and these affected, in order of frequency, the toes, fingers, patella, and radius. There were also noted absence of fibula, hypospadias, cryptorchidism, fissure of palate, and dislocations of various joints.

The femur was in many of the cases normal. Frequently it was somewhat shorter than its fellow, and in one case it was longer. Sometimes it was rotated outward. The lower epiphysis was often undeveloped, the condyles and intercondylar grooves poorly marked. In one case the lower part of the femur was split in two parts, the condyles being entirely separated. In another, the femoral head and pelvis were malformed. The patella was absent in 8 cases certainly, and possibly in 5 more, while in my case it was double. When present, its ligament was inserted in the fibula or in the capsule of the knee joint. Sometimes the ligament was absent, and the patella drawn high upwards by contraction of quadriceps.

In almost all cases there were contractures in flexion and adduction at the knee, and the fibula was generally luxated posteriorly and upward so as to articulate loosely with the external surface of the external condyle of the femur. In two cases it was in the popliteal space. This nearthrosis was lined with synovial membrane, usually continuous with that covering the femoral condyles. It was found well developed even in a fetus. Its ligaments were generally very strong, but the joint had not sufficient stability to carry the weight of the body.

Almost always the crucial ligaments were lacking and the semilunar cartilages as well. The fibula was generally thickened, but shortened, and curved outward and forward, occasionally backward.

If the tibial defect is not total there may be a thin, small hyaline cartilage on the inner half of the joint, and below this the inverted-pyramid shaped rudiment of the tibial head. From the apex of this, a slight band of connective tissue may extend to the astragalus, representing the shaft of the tibia in position, and serving for the attachment of its muscles. In only one instance was there a defect of the upper end of the tibia while the lower end was normal.[3]

The foot is always in varus and the deformity is usually of a high grade, combined with equinus. In a number of cases the number of toes was normal. in five instances the great toe was absent; in several cases two toes were missing. In some there were six or more toes, and these were often on the inner border of the foot. When the fibula is absent, there is often a deficiency of the outer part of the foot, especially the phalanges and metatarsal bones. Where the tibia is absent, the changes on the inner side of the foot are not so constant. In both instances, however, the entire foot may be normal or there may be supernumerary metatarsals and phalanges.

The muscular development presents the greatest possible variety. Some muscles are entirely absent, others atrophied with misplaced origins and insertions, in accord with the defects of the osseous system.

The six cases detailed above are all that have been operated upon by transplantation of the fibula. In none have the ultimate results been recorded. In none of them, except my own, did the ankle joint require the production of an arthrodesis. It would seem that the operative procedure should be selected with a view of preserving motion at the knee. The ankle joint also must be made as stable as possible, more so than a simple tenotomy with correction of the deformity could promise,[4] because not only must it be able to carry the body weight itself, but it must not by its weakness interfere with the function of the knee.

Baudenhauer[13] recently corrected a club hand due to deficiency of radius, by splitting the ulna and inserting the carpus in this cleft. He suggested that this procedure could be carried out in cases of defect of the fibula and tibia also, and Rincheval[38] attempted in a case of absence of tibia to split the fibula and insert the lower end of the femur in the cleft, expecting at a later operation to split the lower end of the fibula and insert the astragalus between

these ends. He divided, however, the popliteal artery, which pursued an abnormal course, and gangrene of the lower half of the leg followed. The deformity in some of these cases is so extreme, owing to the maldevelopment of the fibula, as well as the absence of the tibia, and the muscular contractures are so pronounced that amputation is necessary. However, amputation was done in some of these cases where the limb could have been saved. The attendant conditions, which always must be considered, are unknown to me, and may have made the radical operation necessary.

The cases will be very exceptional where a limb of this kind will not have to wear a high shoe and some splint always. On the other hand, if the leg is amputated, an artificial limb must be worn always, and most people prefer to have a leg of bone and muscle, even if it must always be supported. A stiff knee is most undesirable in a great many ways, therefore an arthrodesis at the knee is to be avoided. Judging from the condition of my patient twelve months after the operation, I shall be much surprised and disappointed if he does not continue to have sufficient stability at the knee, though its motion has been preserved.

# EXAMINATION OF THE RECTUM AND ITS VALUE IN DIAGNOSIS.

By CHARLES J. DRUECK, M.D.,

CHICAGO.

PROFESSOR OF RECTAL DISEASES AT HARVEY MEDICAL COLLEGE; PROFESSOR OF RECTAL DISEASES AND CLINICAL SURGERY AT THE NATIONAL MEDICAL UNIVERSITY; RECTAL SURGEON TO THE PEOPLE'S HOSPITAL; ATTENDING SURGEON TO THE NATIONAL EMERGENCY HOSPITAL; MEMBER OF THE AMERICAN MEDICAL ASSOCIATION AND CHICAGO MEDICAL SOCIETY.

THE examination of the rectum is taken up exhaustively in this paper because many general practitioners overlook details and make but a cursory examination of patients suffering from rectal disorders. I have had many patients troubled by diseases of this region report to me whom the doctor had not even examined. All who have engaged in general practice realize how common rectal disorders are, and how completely the sufferers are invalided, yet with so little pathological change. The general practitioner who wishes to retain the confidence of his patients must examine the rectum as carefully as he would any other part of the body, for the time is past when patients will be satisfied with a placebo and not go to some one else. All modern books on surgery find it necessary to incorporate a chapter on diseases of the anus and rectum. Almost every patient who realizes that he has rectal trouble will inform his physician that he is suffering from piles and, I am sorry to add, many doctors accept the patient's diagnosis and prescribe without ever examining the parts. Rectal diseases are always progressive, and an early diagnosis may mean a slight operation and no absence from business, while later the condition may be so aggravated as to confine the patient to his bed for weeks or months. The object of this paper is to bring before its readers the essentials of an examination of these parts and to assist the physician in making an intelligent diagnosis of his patient's ailment, instead of trusting to luck and a "shotgun" prescription in the form of an injection or application.

The symptoms of rectal abnormalities sometimes draw the patient's attention at once to this particular organ, but again, because of the intimate connection of the rectum and other pelvic and abdominal organs, the symptoms may be so obscure or the onset so insidious that reflex disturbance elsewhere is first complained of, and the patient is treated for disease of some other organ. While the symptoms may refer in general to this part of the body, yet they do not indicate the specific disease, as few signs or symptoms are pathognomonic. The odor of cancer or the pain of fissure are characteristic, but they do not in any way indicate any associated condition or disease. The preliminary interrogation of the patient should be systematic, so as to cover carefully and completely the whole case without repeating. It is a good plan to let the patient tell his own history and for the physician to bring out the patient's age, the duration of the disease, the progress of the symptoms since their appreciation, together with whatever effect they have on the general health. If pain is complained of, ascertain its character, whether it is sharp and cutting, burning, or dull and aching; and its relation to defecation, whether it occurs before, during, or after the passage of the stool; and whether it is constant or intermittent; and its exact location as, at the anus, within the rectum, in other pelvic organs, or in the sacrum, or whether it radiates from a given point. If there are any discharges, their nature, and the presence and amount of blood, mucus, or pus, are important. If blood is present, find out the color, whether dark or bright. The condition of the

sphincters must be investigated as to whether relaxed or abnormally contracted, and if protrusions exist, whether they recede of themselves or must they be replaced, and whether their replacement is difficult or painful. It is important to ascertain the character of the protrusions, as smooth or nodular, or covered with rugæ, hard or soft, and whether it is tender and sensitive to the touch, and whether there are any ulcers present; also whether it occurs only during defecation or is continuously exposed or can be produced at will. Any evidences in the general system of other diseases, such as anemia, tuberculosis, or syphilis, must be taken into consideration; also the condition of the kidneys and bladder, and whether the patient has had gonorrhea or any urethral stricture. If a female, and married, how many children or miscarriages, and was there any rupture of the perineum? Is there any uterine or ovarian pain; any vaginal discharge; prolapse of the uterus, or difficulty in urinating? If a virgin, inquire as to menstruation; whether regular, painful, scant, or profuse.

The occupation or mode of life of the patient may not have been a factor in causing the disease, but it may be important in mapping out his future mode of living as to habits, environment, and diet. Does he use enemas frequently? Does he, like the proverbial Irishman, take his pipe and paper to the toilet with him? Does the rectum feel empty after the evacuation, or is there a desire for further action? Is there a history of sodomy or venereal diseases or any family history of tuberculosis or cancer? The examination of any case, medical or surgical, is incomplete unless we go into the family and personal history. It is often tedious, and much time is wasted on irrelevant matter, but frequently it emphasizes idiosyncrasies.

For convenience, I have arranged all the important items of the examination in abbreviated but comprehensive form in my record sheet. I want to emphasize the importance of keeping these records in even the simpler cases. One never knows what complication or legal tangles may arise in the future. A patient, whom you have forgotten, returns to you after a period of months or years, and, unless you have a record, you may be embarrassed to know just what the diagnosis or treatment was. When you write out a record before your patient, it impresses him with your carefulness, and at the same time it impresses carefulness and detail upon you. I append a copy of my record form that it may serve as an outline for the reader in preparing his own:

Record Sheets.

After the patient has told you his case and you begin to make a mental picture, it must be remembered that in many instances rectal diseases do not have symptoms pointing directly to that region, and that the rectum is not always at fault when symptoms do refer to it, for they may be reflex. A displaced kidney or uterus, urethral stricture or enlarged prostate may incite an irritability of the rectum and necessitate a general examination before one states that the rectum is diseased, or that it alone causes the disturbance. On several occasions I have seen patients who had submitted to rectal operations without obtaining relief from the local symptoms, and who were surprised when informed that the trouble was not in the rectum, but in some other pelvic organ; and who were relieved of these symptoms when the other organ was set aright. Very recently I saw a periostitis of the coccyx, the most annoying symptom of which was a pain and heaviness in the rectum.

*Preparation of the Patient for Examination.*—It is convenient for those treating rectal cases to have a toilet adjoining the examining room, that patients may empty their bowels just before examination. When this is not practicable and only a few rectal cases are seen, a commode which, when not in use, can be screened or easily pushed aside, may be substituted. If possible, a cathartic should be given the day before and the rectum washed out with an enema just prior to the examination. This procedure is absolutely necessary when the upper part of the rectum is to be examined, as otherwise, when the speculum is introduced, the field would be obstructed by feces and a thorough examination could not be made. This is important not only for cleanliness, but also because the straining during defecation brings down hemorrhoids, polypi or prolapse, and thus assists in the diagnosis. Even with these precautions, you occasionally find in a case of impaction the rectum lined with inspissated feces, which, of course, have come down after the evacuaton. Often, however, I prefer to make the examination without this preparation, that I may find the rectum more in its customary condition and that any pus, blood, mucus, or hardened feces may be found more readily. Small protrusions or prolapses often retract within the anus when the patient walks a little, hence, it is sometimes necessary to examine the patient, either on the commode or just after arising, before he takes a step. All constricting bands, clothing, or corsets must be removed or loosened, for they have a tendency to force the bowels into the pelvis. The bladder must also be emptied. It is often necessary to administer an anesthetic to secure a thorough examinations of all parts and fully to relax the sphincter.

Gentleness is important in making a rectal exploration, as much pain may be avoided and spasm of the sphincter prevented. Very much also depends upon the skill of the examiner, because sometimes the ordeal may be very painful, and doubly so if

carelessly performed. Few instruments are needed, and only such as every physician has in his case. In examining the upper portion of the rectum. A speculum and reflected light are necessary. For such an examination an ordinary table is as suitable as a specially constructed one. In regard to the position of the patient, the exaggerated lithotomy, the Sims, and the knee-chest positions each have their special advantages in particular instances. The ordinary dorsal or lateroprone position is all that is needed for digital or specular examination of the lower rectum, although many prefer the exaggerated lithotomy, the patient's hips being elevated by a cushion. The knee-chest is, however, the only position that permits an examination of the higher portions of the rectum. The Sims' position, with the thighs strongly flexed and the breast on the table, the left arm behind the back, inverts the pelvis and allows the contents to fall upon the front wall of the abdomen; the lumen of the rectum tends to gap, and the mucus membrane falls away from the end of the speculum.

*Examination.*—The examination comprises inspection, digital and instrumental examination. Inspection may reveal the conditions which produce various neurasthenic or anemic conditions. The shape of the anus is sometimes important, whether normal, protruded, or drawn in (funnel-shaped), and the amount of pigmentation about the parts. Evidences of abrasions, scratches, pediculæ or worms may be seen on the skin about the anus, also signs of inflammation or scars. A prolapsed rectum may be the cause of prolonged vomiting or pertussis. An ulcer, fissure, or pruritus may excite rectal tenesmus and also produce a scybalous stool. Protruding tumors, condylomata, such as hemorrhoids, polypi or malignant growths may also be seen and their characteristics noted. Very often a distinct fullness or bulging of the anus is seen where internal hemorrhoids are present, even if they do not protrude. Where epithelioma exists at or outside of the anus, a small piece may be clipped off for microscopic examination without any discomfort to the patient by using a little local anesthesia. After carefully inspecting the anus and perineum, the field may be widened by gently pulling the anus open, a hand being placed on each buttock, the finger tips pointing toward the anus. If the patient bears down at the same time, a considerable portion of the mucus membrane will be everted, the extent depending on the relaxation of the sphincters. In this way, the lower inch or more of the bowel may be inspected without the use of the speculum, and a fissure, fistulous opening, gonorrhea in women, syphilitic erosions, eczematous excoriations or pin-worms may be brought into view. In many instances the internal opening of a fistula is situated immediately within the external sphincter, and, in such a case, it may be seen by this procedure. During this maneuver, any tender or indurated areas may be mapped out. Fistulous tracts are thus easily followed up without the use of the probe. In women who have lax sphincters, a portion of the interior of the rectum may be everted by introducing the index finger into the vagina and pressing the rectal walls out through the anus. The presence of a discharge issuing from the anus indicates disease within the rectum; while the sunken ischiorectal fossæ and retracted anus surrounded by a profuse growth of soft hair would immediately suggest malignant disease within the rectum, or tuberculous disease, with general systemic involvement.

*Digital examination* of the interior of the rectum follows inspection, and it is the most important of all methods. The practitioner who is familiar with the digital examination of these parts can diagnose better with his finger than by any other way. Fully 80 per cent. of all rectal cases may be diagnosed with the finger and the other 20 per cent. by the history of the case and a specular examination. Digital examination not only confirms the opinion regarding the local conditions found by inspection, but also determines other conditions to which attention may have been directed. The finger should first be swept around outside of the anus to palpate any induration or tenderness, either superficial or deep, which might indicate abscess or fistula. For internal examination the finger-nail should be well trimmed and the finger anointed with olive oil, which is not so easily rubbed off as soap or vaseline by the sphincter. Whatever lubricant is used must be kept in collapsible tubes, as this is the only method of having clean, sterile lubricant at all times. The cost is little and the advantages great over the old-fashioned jar of vaseline into which fingers and instruments were repeatedly dipped, carrying infection from one patient to another. For esthetic reasons, the rubber tissue cot may be worn if desired, because it will not affect the sensibility of touch and may be washed and anointed. The finger is then gently insinuated through the anus with a rotary or boring motion, the patient being asked to bear down at the same time, and the rectum systematically palpated as high as the finger will reach. The introduction will be rendered much easier if the course which the rectum follows is remembered, and the finger is first directed up and forward toward the neck of the bladder, until the sphincter is passed, and then backward toward the sacrum. The sphincter is very sensitive, and undue haste or roughness may induce spasm of that muscle, which will make the examination very painful and unsatisfactory. The iliac fossæ should be firmly explored to determine whether there is any tenderness or tumor. The finger should be introduced its full length, and, by passing the other fingers of the hand back into the intergluteal space instead of doubling them into the palm, an increased reach is obtained; also if the patient bears down or strains during the examination, one or two inches more of the rectum can be examined.

The condition of the sphincter should be noted; whether it is relaxed, suggesting a debilitated system, cancer, or large internal hemorrhoids, which, by frequently protruding, weaken the muscle; or contracted, signifying acute disease in the anal canal, anal fissure, or a nervous subject; or whether hypertrophied, denoting chronic disease, or atrophied. The spasmodic action should be overcome by slow, steady pressure, as the sphincter is always forcibly contracted on attempting examination. Frequently the internal opening of a fistula is found just within the sphincter, as a rough, indurated, and sensitive spot which may be elevated or depressed (ulcerated), or the path of a sinus is felt by its cord-like resistance. If a tumor is felt, its size, shape, location, movability, and resistance are to be ascertained and, if possible, a small piece removed later through the speculum for microscopic examination. Fecal impaction of the rectum or colon has often been mistaken for cancer. Gallstones or foreign bodies, polypi, stricture, and abscesses are occasionally felt. The tumor of appendicitis is found in the pelvis to the right, if the appendix is low, and rectal palpation should be practiced in every case of suspected appendicitis. Malignant disease of the rectum or pelvis, the tumor of intussusception and an infected lymph gland also may be felt. A digital examination carefully performed is not painful unless a fissure is present. Induration or constriction of the walls and the condition of the other pelvic organs may be determined.

Palpation of the prostate reveals enlargement, induration, tenderness or soft points, if present. The uterus and appendages should always be examined. Vesical irritation is a frequent source of reflex disturbance, and the bladder always should be examined. A stone may be found to be the origin of the trouble, although no symptoms were manifested. A digital examination through the rectum often assists considerably in diagnosing diseases of the urethra, Cowper's glands, seminal vesicles, bladder, vagina and pelvic bones; also tumors and abscesses of the peritoneal cavity, dislocation of the femur, ischial hernia and aneurysms of the gluteal artery. Very little information is gained by digital examination regarding hemorrhoids, except in rare cases, where much hypertrophy has occurred in the mucous membrane. Otherwise, the hemorrhoid being covered with nearly normal, mucous membrane, gives no differential tactile sensation. Thus, you see, a digital examination through the rectum is imperative in any case indicating disease below the pelvic brim. On withdrawal, the finger may be covered or streaked with blood, pus or mucus, each with its own significance. If a stricture is so small as not to admit the passage of the finger, no force should be used, as rupture of the bowel has followed such an attempt. The cervix, the fundus of the uterus, or the prostate may be mistaken for a tumor. In rare instances, it may be necessary to introduce the whole hand into the rectum, but as the walls are so crowded upon the fingers and the folds of mucous membrane fall in between the fingers, very little knowledge is obtained, and there is always the danger of rupturing the bowel. A laparotomy and intraabdominal palpation is preferable when the disease is high in the rectum or in the sigmoid.

*Instrumental Examination.*—Bougies. That part of the rectum beyond the reach of the finger may be examined by means of bougies or sounds, although their use is purely speculative and is often contraindicated. Only soft and flexible instruments should be used, and these must be handled with the greatest care and caution. They should be hollow, to permit the injection of fluid through them into the part beyond, thus dilating the rectum in advance and effacing any folds that might obstruct their introduction. Too great value must not be placed on bougies, as their field of usefulness is limited, and even in a healthy bowel the sensations of obstruction often are obtained and may be misleading. I have yet to see a student who did not find a stricture the first time he introduced a bougie, because the sound often impinges on the wall of the bowel between the folds of the gut, and a stricture is erroneously diagnosed; or it may strike the uterus or prostate, or the promontory of the sacrum. There is always danger of a metal or hard rubber sound penetrating the bowel, especially in cancer or ulcerations. Sometimes the so-called third sphincter, which is only a semilunar, transverse fold of the anterior and the right sides of the rectum about six or eight centimeters above the anus, may catch the bougie. Normally the bougie may be introduced with care to the middle of the sigmoid flexure. If the mesocolon of the sigmoid is very long, the bougie may be felt on the right side and lead the examiner to think it had perforated the bowel. Probes.—The probe has no place in the diagnosis of rectal diseases and very little in the treatment, except in fistula. Even here its value is very limited. Irrigations and injections are sometimes used for diagnostic purposes, and are best accomplished in the knee-chest or dorsal position. Specula.—The speculum corroborates the digital examination and aids in the diagnosis where the finger fails, but by no means supersedes the latter. It is indicated where obscure hemorrhage, pain, or discharge is an important symptom. The internal openings of the fistula may be seen, especially if the discharge escapes during instrumentation. Internal hemorrhoids usually drop into the instrument and are seen easily. As to which is the best speculum, the decision depends upon the one you are most familiar with. A large variety of specula are on the market, and each one is differently constructed, but the more rectal examinations you make the less you will use the speculum. The smooth blade bivalve causes much less pain than the wire blades, but it obstructs the field of vision and exposes only a small field at one time, and the speculum must be rotated. Bivalve specula may be used without an anesthetic or without previously relaxing the sphincter, but are not as satisfactory as the cylindrical specula. By putting the patient under the influence of a general anesthetic, many of the obstacles to the examination are removed and the field may be explored thoroughly; the sphincter completely relaxes, pain is obviated, and in such cases it is well to be prepared to do any necessary surgical treatment in order to avoid a second anesthetic. The cylindrical speculum permits of the most thorough work. With the patient in the knee-chest position and a speculum five inches long and one inch in diameter, the whole length of the rectum may be examined. Such a speculum is provided with an obturator to facilitate its introduction, which should be accomplished without much pain. When the obturator is withdrawn, the air rushes in and dilates the bowel, and the whole rectal wall may be inspected by moving the introduced end about, at the same time gradually withdrawing the speculum. The mucous membrane directly in front of the speculum is flattened out and viewed easily by gently pushing up the speculum after the obturator has been removed. When the patient is anesthetized, however, and the sphincter well relaxed, the lower part of the rectum may be examined quite as well by using an ordinary wide retractor. A speculum ten or thirteen inches long may be introduced, if with care, and the sigmoid explored, but as the great majority of rectal troubles are near the anus, a short and wide speculum is preferable. A good reflected light affords the best illumination. When assuming the knee-chest position, the chest should be well down on the table and all constrictions at the waist must be removed. Forcible overdistention of the sphincter, causing temporary paralysis, is often necessary and sometimes facilitates the after treatment. It may be done either with the fingers or a speculum. The incontinence that results usually passes off in a short time, provided the sphincter is not torn. Dilation is practiced by introducing both thumbs well into the rectum and grasping the buttock on each side with the fingers and then drawing the thumbs laterally until they touch the ischial bone. The stretching should be performed slowly and in every direction, for, if performed rapidly, some laceration will surely result. The sphincters remain partially paralyzed for a week or more.

The methods of examination of the anus and rectum have each been detailed and their merits and demerits compared. We have tried to show the importance of care and thoroughness in this work, and trust the reader may find his interest in this particular branch of surgery increased. Almost every day the writer is impressed with the lack of attention given to rectal diseases by the general practitioner. Surgery of the rectum especially interests the doctor and patient, because much of the work may be accomplished in the office and under local anesthesia, and the results of careful work are both positive and prompt.

New York, July 15, 1905.

## HYGIENIC WISDOM.

AMONG the many things which various writers call this the age of, we may safely say that hygiene, especially individual hygiene, is one. Books without number are printed, many of them very sound, telling how to live long, how to get strong, how to breathe, how to eat, how to sleep, and how to do many other things that the natural man would rightly do by instinct. Many of the magazine and Sunday newspapers devote a column or more in each issue to discourses on health topics, and regular lectures are given in most of the higher schools on like subjects. In addition to these more or less orthodox expounders of personal hygiene, we have a horde of health cranks and food faddists—the "simple livers," who go about as nearly naked as the authorities will permit; the "mother earth" cranks who sit in holes in the ground for hours at a time so as to catch the vital principle which they assume makes the grass grow; the vegetarians, who, in these days of fruitarians, grainarians, nutarians, and raw-foodists, must be ranked among the riotous livers, and a host of others, who bear witness to the fact that this is the age of pseudohygiene at least.

The human frame can stand a good deal of abuse, inside and out, and it is probable that the food fads and the fool faddists do not injure very many and may do some good to a few; and unquestionably the advice given by the orthodox preachers of right living is sound in the abstract, but not always easy of application in the individual case.

In a very sane article on "Individual Factors in Hygiene," published in the *Boston Medical and Surgical Journal* of June 15, Drs. R. C. Cabot of Boston and P. K. Brown of San Francisco point out that there can be no rules of individual hygiene applicable to all, and that, in fact, in regard to this science, we are in one of those periods of not infrequent occurrence in any growing science when we know less than we used to know, or, rather, to think we knew. It is beginning to dawn upon us that in the matter of personal hygiene, as in other personal matters, what is one man's meat is another man's poison, and that the rules of sanitary conduct which are valid for all men are lamentably few and lamentably vague.

The writers in the Boston *Journal* make it very clear that in approaching this question of hygiene as applied to the individual there are several important factors to be taken into consideration. In the first place, one must know what are the ideals of the individual. One man may be of studious inclination, and may wish to know only how best to preserve health while devoting all the time possible to his literary pursuits. Another may want to get all the "fun" he can out of life without going so far as to bring it to a premature end. Still another may desire to go in for athletics, but not so strenuously as to cripple his heart. The physician may have his own notions as to which of these ideals is the best, but he must yield to the desires of his patient and must be ready and able to guide him along the road he has chosen. If the patient wants to go to Chicago it is not for the guide to advise him to go to Boston, but to point out to him the most comfortable and the safest road to take to reach the goal he has chosen. Other more familiar factors are those of age, sex, station in life, occupation, race, physique, and climate. The necessity of taking all these into consideration in advising upon the mode of life is self-evident, yet it is often ignored by the physician who is too prone to take his individual likes and idiosyncrasies as a standard to which he would make all his patients conform. In speaking, then, of personal hygiene it is clear that the accent should fall with fully as much emphasis on personal as on hygiene.

The hygiene of the future, Drs. Cabot and Brown aver, will not be a series of commands to do this or not to do that, without regard to the condition of life, the temperament, or the will of the individual, but "a map showing a number of practicable roads, each preferred and found satisfactory by a group of persons of a certain build, a certain ideal of life, a certain inherited and acquired set of tissues." Such a map is as necessary to the man who would live right and live long in his chosen sphere as a road map is to the cyclist or the autoist, and it is the authors' ambition "to assist in the construction of this map, to find out by the collection of an enormous body of statistics of healthy people what workable sets of habits now exist in regard to food, water, exercise, sleep, work, recreation, and the rest. Such a map of passable roads will not bind the individual to walk on any one of them, but if he wishes to roam in the fields or ditches he will at least be conscious of what he is doing and where the ordinary roads are if he cares to return."

Drs. Cabot and Brown have blazed a new path, and one that promises to lead somewhere, for the need of individualization in hygiene is only too apparent to one who reads the conflicting rules formulated by writers on health matters. If the authors of this thoughtful article succeed in the task they have set themselves, and are able to fill in the details of such a health map as they have outlined, the man who loves living as much as he loves life will have cause to call them blessed.

## THE PORTLAND MEETING.

THE meeting of the American Medical Association in Portland, Ore., which is still in session as we go to press, promises to be among the more successful of the gatherings of members of this society, if success is to be measured by numbers. The Lewis and Clark Exposition, which is now under full swing in Portland, probably drew a few visitors, but the chief attraction—and a very potent one for those of us who live east of the Mississippi River—was the opportunity afforded the members to see some of the wonders of the West in pleasant company and at moderate cost. Many of the eastern delegates clubbed together, forming special parties in special trains,

stopping either going or coming at Denver, Yellowstone Park, San Francisco, and other places of interest. The largest attendance, as is always the case, was drawn from nearby places, in this instance the entire Pacific Coast sending many to Portland. It is eleven years since the Association met west of the Rocky Mountains, and a gathering there was needed to arouse interest in the Association and to demonstrate to our western confrères that it is not a local Chicago society.

The very complete telegraphic report of the early proceedings, prepared by our staff of special correspondents, and published in the present issue of the Medical Record, will show that the scientific work of the medical and surgical sections bids fair to be up to the usual average of these gatherings. The all-absorbing topic of interest to the members and delegates seems to have been that of the character of advertisements in the *Journal of the American Medical Association*. For a long time, as is known, the Secretary-Editor was a notorious sinner in his readiness to accept the advertisements of proprietary remedies, and until the Editor of the *California State Journal of Medicine* began to hold him up to reprobation he seemed to be an incorrigible sinner. Finally, however, the latter's exhortations had the desired effect, and now there is apparently no more earnest advocate of publicity in drug manufacture than the Editor of the Association *Journal*. His sudden conversion has quite overpowered the converters, however, and their joy at Portland was almost hysterical in its manifestations. The advocates of open formulæ are working for a laudable object, and we would welcome the day when all proprietary remedies should be as definite of composition and proportions as Dover's powder, the makers depending for success upon their skill in manufacture. There is, however, a wide difference between a secret or semi-secret remedy advertised only to physicians, even though the makers are somewhat extravagant in their claims, and one that is advertised in the daily papers and palmed off upon the public on the strength of fraudulent certificates. To class the two together as nostrums or quack medicines is not the way to make converts to pharmaceutic righteousness.

## The Diagnostic and Prognostic Significance of the Diazo-Reaction.

While by no means so valuable from the diagnostic standpoint as the agglutination phenomenon, the diazo-reaction described by Ehrlich is still deserving of a certain degree of recognition in this connection. Although present in the overwhelming majority of cases of typhoid fever, it is, however, not specific of or peculiar to this disease, being observed also in many cases of measles, in a considerable number of tuberculosis, and in conjunction with other affections, especially puerperal septicemia. It has further been thought to have some prognostic significance in relation particularly with tuberculosis, its presence being considered a less favorable indication than its absence. Observations with a view of corroborating or correcting these opinions have been made on a large scale by Mr. Chas. W. Budden (*British Medical Journal*, May 6, 1905), who studied the diazo-reaction in 3,000 persons, 600 in health, and 2,400 suffering from various disease states. A negative response was obtained with the urine from all of the healthy persons, and in 564 cases of various acute maladies, while a positive response was obtained in 96 of 672 cases of various forms of tuberculosis, in 18 of 25 cases of measles, in 17 of 21 cases of typhoid fever, in all of 5 cases of typhus fever, in 4 of 41 cases of acute lobar pneumonia, in 1 of 16 cases of acute bronchopneumonia, in 1 of 96 cases of acute bronchitis, and in all of 4 cases of puerperal septicemia. The cases of pneumonia and bronchitis were eventually found to be complicated by underlying pulmonary tuberculosis. In many cases the test was made daily, and in none was it made less frequently than twice a week. Death occurred in nearly all of the cases of tuberculosis that yielded a positive reaction, but these were precisely the cases in which no hope of a favorable result could be entertained. In many cases yielding a positive reaction the course was rapid, but in an equal number it was slow, and in some improvement even took place. The appearance and disappearance of the reaction coincided respectively with exacerbations and remissions in the tuberculous process. The reaction was absent further in cases that had exhibited improvement in their clinical course, and it disappeared at times because the patient was growing weaker. On account of the inconstancy of the reaction, the conclusion must be accepted that it is of no value in the prognosis of chronic tuberculosis.

## The Effects of Hydriatic Procedures of Short Duration.

A great many observations have been published with reference to the influence of hydrotherapeutic procedures on the circulation, and particularly on the blood pressure. Less attention, however, seems to have been given to their effects on the respiration, so that a recent paper by Brieger and Herz, in the new *Zeitschrift für Experimentelle Pathologie und Therapie*, should prove of particular interest. The effects of various circulatory stimuli have heretofore been studied by the aid of the sphygmograph, but this has proven very unsatisfactory, as the results are by no means constant and often difficult to interpret. A novel method for recording the effects was adopted by these authors, who employed for the purpose a kymograph, by which both the respirations and pulse of healthy normal individuals were registered continuously for a period extending before, during, and after the application of the hydriatic procedure. For recording the pulse they used a Gaertner's apparatus, which takes account of the entire change in the circumference of an extremity and is, therefore, much more efficient than the usual type of sphygmograph. In the collected phenomena induced by thermic stimuli, the respiration was shown to be affected in various ways. The character of these effects varied not only with the temperature, but more especially with the suddenness with which the stimulus was applied, with the particular nerve area involved, and with the sensitiveness of the individual. The application of intense cold to the skin, by means of a lump of ice, was followed by a marked acceleration of respiration, particularly if the sole of the foot were selected for the application. The results were somewhat more inconstant if an extremity was plunged into cold water, the respirations in some cases being slow and deep, in others the very opposite. Regarding douches, it may be stated that in general the usual effect was a strengthened inspiration, without any well-marked stimulation of the expiratory mechanism. No uniformity whatever resulted from the application of various forms of heat. The effects on the pulse of the application of cold were rather interesting, the evaporation of even a small quantity

of ether on the skin, producing a well marked inhibitory action. The sudden application of cold water to any one part of the body produced, first, an increase, then a diminution of the pulse rate. The brief application of heat resulted in a very irregular reaction, only the warm spray producing a regular acceleration of the pulse rate.

### Hospital Ships in War.

Much of practical use should be gathered from the employment of hospital ships in the present war. As yet, however, no exhaustive export has been issued from either Russian or Japanese sources with regard to the value of hospital ships. It is known that the Japanese navy is supplied with excellently equipped vessels of this description, and it is more than conjectured that their utility has been demonstrated, but for an exhaustive account of the manner in which they have served their purpose, we must probably wait until the end of the war. In the *Journal of the Association of Military Surgeons* for June Dr. William C. Braisted, surgeon in the United States Navy, writes on the U. S. naval hospital ship *Relief*, with notes on hospital ships in general. Dr. Braisted points out that while a vessel can be fitted out as a hospital ship with a fair measure of success, the ideal hospital ship must be built and equipped solely for the treatment and care of the wounded. The writer thinks that to be efficient, a hospital ship should be of sufficient size to give room and stability—of not less than 4,000 or 5,000 tons displacement, with a length of 350 to 450 feet. There should be at least three of her decks clear and unobstructed for the purpose in view. There should be two complete decks for hospital purposes, the main deck and the upper deck, which should be divided into four grand divisions, each division constituting a ward with its adnexa, while the contagious ward should be aft and isolated. A spacious operating room should be fitted on the upper deck, with skylights overhead, and adjoining should be the sterilizing room, anesthetizing and recovery room. The transportation of the sick and wounded from a battleship at sea is a problem looking for solution, but it is likely that valuable lessons will be learned concerning this as well as the construction, equipment, and management of hospital ships from the reports of Japanese naval surgeons at the close of the present war.

### Antitoxin Horses.

The widespread employment of antitoxin in diphtheria should create an interest in information regarding the sources from which it is derived. The horse is the animal now most commonly used in the preparation of the commercial article, and the manufacture has been carried in for so long a period that statistical information has become available. W. R. Hubbert (*Journal of Experimental Medicine*, Vol. VII, No. 2) has found that better results in the production of diphtheria antitoxin can be obtained with greater experience in the selection of the most suitable types of horses. Young animals, it seems, are usually to be preferred. Over one-half of all such horses can be made to yield 300-unit serum, while a third will yield 500-unit serum. High test horses require a shorter time to immunize and will yield a potent serum for a longer period than will low test horses. The period of usefulness of an antitoxin horse is short, and, on the average, endures only a few months. A horse having attained a maximal antitoxin height begins to suffer a decline in antitoxin, which is usually as rapid as was the ascent, and is unaffected by subsequent injections of diphtheria toxin.

## News of the Week.

**New Jersey State Board of Medical Examiners.**—At a meeting of this board, held at Long Branch, July 5, fifty-five candidates, who passed the state examination at Trenton on June 20 and 21, were duly licensed to practice medicine and surgery in New Jersey. The medical license of New Jersey is endorsed by the states of Maine, Vermont, Delaware, Virginia, Illinois, Michigan, Minnesota, Kansas, and Colorado, but not by New York. The refusal of reciprocity by New York is naturally resented by the State Board of Medical Examiners of New Jersey, and at this meeting the following resolution was adopted: "*Whereas*, The educational and examining standards for the medical license of New Jersey are at least equal in all respects to those of New York, and in some respects higher, and *Whereas*, The degree of unreasonableness in the matter of interstate endorsement on the part of New York cannot be further ignored, therefore be it *Resolved*, That on and after October 16, the date of the next regular meeting of this board, the endorsement of medical licenses issued by New York will be suspended until further notice." The refusal of New York to endorse the New Jersey medical license is unneighborly, and so far as appears on the surface, unreasonable. Its effect will be to retard the coming of general interstate reciprocity, in which, until the establishment of a national licensing board, lies the only hope of relief from the present awkward system of state institutions. The new officers of the New Jersey Board of Examiners are: *President*, Dr. Edward Hill Baldwin, Newark; *Secretary*, Dr. E. L. B. Godfrey, Camden; *Treasurer*, Dr. Charles A. Groves, East Orange.

**Resignation of Dr. Pryor.**—The Board of Managers of the New York State Hospital for the Treatment of Incipient Tuberculosis has appointed Dr. Melvin Page Burnham of New York City acting superintendent, to succeed Dr. J. H. Pryor, resigned. Dr. Burnham has been for three years resident physician of Seton Hospital at Spuyten Duyvil. The cause given by Dr. Pryor for his resignation was that there was too much red tape in the administration of the hospital, and that while he was the responsible head of the institution, too much power was in the hands of the fiscal superintendent at Albany.

**Filtration of the New York City Water Supply Recommended.**—Health Commissioner Darlings is about to submit to Mayor McClellan a comprehensive report on the city's water supply, and urging the taking of immediate steps for the construction of a municipal filtration plant, which it is estimated will cost about $10,000,000. It is expected that the report will recommend the construction of sand filtration beds near Tarrytown, on a plan similar to the extensive plant now being installed for Philadelphia at Torresdale, Pa.

**Hospital Boat for the Health Department.**—The hospital ship *Claudine*, which is being constructed for the city at a cost of $70,000, will be ready for launching in a few weeks. Her principal duty will be the transfer of contagious disease patients from the hospitals at the foot of Sixteenth street and One Hundren and Thirty-eighth street to North Brother Island, but in addition she will be equipped to serve as a fire boat and will be provided with water tanks so that in case of accident to the pipe lines connecting the islands with the city an adequate supply of water can be transported.

**Federal Regulation for Cooking.**—At the meeting of the International Stewards' Association, to be

held in Chicago, a movement is to be started for the purpose of asking congress to make legal provision for a national school on food, cooking, and service. More than two thousand chefs, stewards, restaurant men, and hotel-keepers are interested in the project, which has for its object pure food for the public, natural methods in cookery, and sanitary ways of serving food. Germany inaugurated the national system of control a long time ago, but this is the first effort in the United States to have congress recognize that national cooking needs to be of the highest order to maintain national good health.

**Trouble in California.**—There has been a revolt organized against the Medical Society of the State of California on account, chiefly, of the action of the State medical examiners, who are appointed from among the members of that society. Charges have been brought against the examiners of the society of attempting to establish a medical trust, and against certain members, of conducting unfair examinations, the assertion being made that certain colleges are discriminated against in favor of the University of California. On the ground that the articles of incorporation of the old Medical Society of the State of California were not properly issued, and that the method of incorporation did not comply with the statute as required by the law on corporations at that time, a new Medical Society of the State of California had applied for articles of incorporation and been refused by Secretary of State Curry, on the ground that the name belongs to the old society. The object of the new incorporators was, of course, to obtain recognition for their organization on the legally constituted State medical society, and so to take away from the old society the appointment of medical examiners.

**The Ohio State Medical Union** is the name of a new society recently established in Columbus, Ohio. Any legally qualified practitioner of medicine, of no matter what school of practice, is eligible for membership. It will be affiliated with the American Medical Union, a national society organized six or seven years ago along the same lines. The president of the new State society is Dr. H. L. Kutchin of Columbus.

**A Solution of Radium Emanation.**—Mr. Colin, a Russian experimenter, claims to have effected a stable solution of radium emanation in distilled water, from which believers in the therapeutic virtues of radium hope for hitherto unattainable good results.

**Clarke County (Ga.) Medical Society Formed.**—This society was formed at a meeting held June 28, in Athens, and the following officers were elected: *President*, Dr. James C. Bloomfield; *Vice-President*, Dr. D. D. Quillian; *Secretary-Treasurer*, Dr. H. M. Fullilove; *Board of Censors*, Dr. I. H. Goss, Dr. S. H. Dillard, and Dr. Echols.

**Ambulance Accident.**—The Seney Hospital ambulance, while responding to a call, was upset by collision with a trolley car at Fourteenth street and Third avenue, Brooklyn. Drs. A. C. Hutchinson and Henry Zimmer of the house staff, as well as the driver, were thrown out and struck on their heads some distance from the wreck. All three were painfully but not dangerously injured.

**American Institute of Homeopathy.**—At the sixty-first annual convention of this association, held in Chicago, the following officers were elected: *President*, Dr. S. H. Aurand, Chicago; *First Vice-President*, Dr. J. N. Downs, Ottawa; *Second Vice-President*, Dr. Mary Hanks, Chicago; *Secretary*, Dr. Burton Hazeltine, Chicago; *Treasurer*, Dr. E. C. Sweet, Chicago. Chicago was chosen as the next meeting place of the convention.

**Hot Weather in Italy.**—The heat in Italy is phenomenal in intensity this summer, and over 800 cases of heat prostration have already been reported. The temperature in the square before St. Peter's in Rome is said to have reached 109°F. in the shade.

**Yellow Fever on the Isthmus.**—No cases of yellow fever have been reported since June 25. Only four deaths from this cause occurred among the employees during the month of June, and only two of these were appointed in the United States. Work on the water works and sewerage system is being pushed with much energy, and about 1,400 laborers are now engaged in this department.

**The German Surgical Society.**—The next annual meeting of this society will be held in the Langenbeckhaus, Berlin, April 18-27, 1906. The presiding officers will be Professor W. Körte of Berlin and Küsten of Marburg; the secretaries Drs. W. Körte of Berlin and Kümmel of Hamburg; the treasurer, Prof. Köhler of Berlin.

**The World's Fair in Milan.**—An international exhibition of applied sciences and manufactures is to be held in Milan in 1906, to celebrate the completion of the Simplon Tunnel. The exhibition grounds consist of 199 acres at the northwest of the city. The buildings will cover 42 acres. The scheme is being carried out under government and municipal patronage. Among the others there will be a section on hygiene where will be grouped all the exhibits relating to hygiene, therapeutics, and preventive medicine.

**The Dangerous Headache Powder.**—The death of a woman in Philadelphia as a result of taking a popular headache powder and the occurrence of a death from a like cause in Chicago call renewed attention to an evil for which there should be a ready remedy. Legislation should long ago have been enacted forbidding the sale of medicinal substances the exact constitution of which is not known or is not explicitly stated.

**Bequests to Hospitals.**—In the adjudication of the estate of Anna H. Wilstach of Philadelphia the following awards were made by the Orphans' Court from the balance of the annuity fund: Hospital of the Protestant Episcopal Church, $6,624.42; Protestant Episcopal City Mission, for the use of the Home for Consumptives, $6,624.43; Pennsylvania Hospital, $6,000; Howard Hospital, $624.43.

**Pennsylvania State Department of Health.**—All of the medical examiners in the Pennsylvania Railroad Voluntary Relief Department and also all of those connected with the Philadelphia & Reading Railway Relief Association have been appointed special medical inspectors for the two railroads by Dr. S. G. Dixon, State Commissioner of Health.

**The Washington Heights Hospital,** incorporated in June, 1905, will be a non-sectarian hospital, supported by voluntary subscriptions and annual donations. It is located on Broadway, between 178th and 170th streets. The medical board consists of Drs. Henry M. Kalvin, president; C. Clarence Sichel, Joseph Weinstein, Stanley O. Sabel, P. William Nathan, Leon Borman, I. Friesner, and Louis Rodenstein.

**The Highland County (Ohio) Medical Society** met in Hillsboro, O., July 5. Papers were read by Drs. C. C. Croffer, of New Market; J. N. Ellison, of Sardinia, and H. A. Russ and W. W. Glenn, of Hillsboro.

**Cincinnati Hospital Pathologist.**—The Board of Public Service, at the request of the medical directors of the Cincinnati Hospital, has passed a resolution that hereafter the professor of pathology of the

Cincinnati University shall be at the head of that department of the Cincinnati Hospital.

**The California State Board of Dental Examiners** has recently been thrown into a condition that may be compared to cyclonic agitation. Some people charge that they have been sowing the wind and that the harvest is now ripe. An official investigation will be made in August. The board has always consisted of two parts, the "solid three" and an uncongealing two. Recently one of the minority publicly accused a member of the majority of having furnished his questions and answers to favored applicants several days before the examination was held, and it was this charge that led the governor to appoint a commission to investigate. But a possibly more serious difficulty confronts the board in the form of a suit for $50,000 damages for the arrest of a dentist, said to have been licensed and wrongfully accused. No licenses have been issued to the successful applicants in the recent examination at San Francisco; the attorney of the board has been dismissed, and its executive committee has been "dissolved."

**Commission for Missouri State Sanatorium.**—The committee to select a site for the new state sanatorium in Missouri for the treatment of incipient tuberculosis has been appointed, the following gentlemen constituting the committee: Drs. W. M. Bayless of Macon, J. L. Eaton of Bismarck, L. C. McElwee of St. Louis, W. L. Gupton of Montgomery City, and W. D. Craig of Galena.

**Charges Against a Health Commissioner.**—Charges have been preferred against the Health Commissioner of St. Louis that he has failed to give his entire time to the duties of his office; that he has abused his power in the appointment and removal of subordinates, and has unduly interfered with the duties of the superintendents of institutions under his control.

**"Surgery, Gynecology, and Obstetrics"** is the name of a new magazine which appeared in Chicago this week. This new publication will be issued monthly. The managing editor is Dr. Franklin H. Martin, and the associate editor Dr. Allen B. Kanavel.

**The California Pharmacy Law.**—An amendment of the law in California that became operative on July 1 forbids anyone to conduct a drug store unless he employs at all times a registered pharmacist. Assistant pharmacists are forbidden to compound prescriptions or to sell any poisonous drug or chemical. The licensed pharmacist must record such sales and obtain the signature of the purchaser. The state board of pharmacy is given power to regulate the quality of drugs sold, and the appointment of an inspector is provided for whose duty it shall be to make periodical investigations of the manner in which the law is being obeyed by the druggists. Another section of the law prohibits all pharmacists from working longer than ten hours a day during any six consecutive days.

**Los Angeles County Hospital.**—The recently installed internes of this institution are Drs. D. D. McKellar, J. H. Hall, Walter Bayley, and J. H. McArthur, all of them recent graduates from the medical department of the University of Southern California.

**American Hospital for Turkey.**—The trustees of the American Hospital and Training School for Nurses to be established at Constantinople, Turkey, at a recent meeting adopted plans for the foundation of the hospital.

**Death of Prof. Nothnagel.**—Prof. Hermann Northnagel died at Vienna on July 7 at the age of sixty-five. During his illness he kept a record of his symptoms, and the notes found in his room describe his sensations until shortly before death came, including observations on the prodromal signs in three severe attacks of coma.

**Prof. Mikulicz Dead.**—On June 14 Prof. Johannes v. Mikulicz-Radecki died in Breslau at the age of fifty-five, after a painful illness. Obscure pastric symptoms had given him uneasiness for some months, when, early in December, 1904, he discovered a hard mass in the region of the stomach. In order not to mar his family's enjoyment of the holidays, he said nothing about his condition until after Christmas, and on January 7 at an exploratory laparotomy it was discovered that the pylorus was involved in a malignant growth so adherent to the pancreas and colon as to be inoperable. He accepted the verdict with unexampled fortitude, and caused the report to be circulated that the operation had been done for the relief of an umbilical hernia. After a very short period of convalescence he resumed the full routine of his professional and clinical work, but in April, after a severe hematemesis, had to give up, and became progressively weaker until his death occurred. It was a tragic perversity of fate to decree that a man who had contributed so much to the surgery of the stomach should himself fall victim to a carcinoma that when diagnosed was too far advanced to be operable.

**Obituary Notes.**—Dr. James H. Close of St. Louis was killed in his home on the night of June 15. He was found with a bullet hole in his breast, but it could not be established whether he committed suicide, or was murdered, or killed by accident. Dr. Close was an expert marksman, and was in the habit of practising in his rooms, where he had a practice range fitted up. He was very eccentric, and had his home and grounds wirder in an intricate manner to prevent invasion by burglars. Dr. Close was born in Canada in 1845. He was graduated from the College of Physicians and Surgeons of Kingston, Ontario, in 1873. He was a Fellow of the Royal Microscopical Society of London, and professor of microscopy and pathology in Barnes Medical College, St. Louis.

Dr. Charles W. Robbins died at Philadelphia on July 4, at the age of 70 years. He was a retired surgeon in the United States Army.

Dr. George L. Fanning of Port Jefferson, L. I., died July 6, in Brooklyn, after an operation for the removal of a gastric tumor.

Dr. Roger Q. Drake of Mt. Sterling, Ky., died June 29, at the age of 59 years. He was a graduate of the Jefferson Medical College, Philadelphia, in the class of 1868.

Dr. Robert S. Briskoe of Colorado City died on June 25, at the age of 72 years. He was a graduate of the Medical Department of Washington University, St. Louis, in the class of 1857.

Dr. Pascal H. Sawyer of Cleveland, O., died June 26, at the age of 68 years. He was born in Brimfield, Ohio, and was a graduate of the Western Reserve Medical School in the class of 1850. He practised for some years in Kent, removing to Cleveland in 1871. He left three sons, one of whom, Dr. John P. Sawyer, is a practising physician in Cleveland.

Dr. Samuel H. Leeman of Dallas, Tex., died July 5, at the age of 38 years. He was a graduate of the St. Louis College of Physicians and Surgeons in the class of 1898.

Dr. George H. Wilson, a colored physician of Cleveland, Ohio, died of Bright's disease on July 3, at the age of 35 years. He was a graduate of the Western Reserve Medical School in the class of 1893.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

ROYAL COLLEGE OF PHYSICIANS—HARVEIAN ORATION—PRESENTATION OF MEDALS—SLEEPING SICKNESS—HOSPITAL APPEALS—CHAIR OF PATHOLOGY AT OXFORD—OBITUARIES.

LONDON, June 23, 1905.

THE Harveian oration was delivered on Wednesday afternoon at the Royal College of Physicians, the orator this year being Dr. Frederick T. Roberts. The praise of Harvey is a well-worn theme at the college, and it must sometimes puzzle the orator to give it freshness. But the memorial is not confined to Harvey, for his will directed the oration to commemorate all the benefactors of the college with an exhortation to others to imitate these benefactors, to search and study out the secrets of nature by way of experiment with other excellent exhortations.

Dr. Roberts assigned a number of reasons for commemorating Harvey, besides his great discovery of the circulation. Harvey exhorted physicians to continue the work of research, and this had been done by the great body of medical men, who followed him. Antivivisectors have taken to patronizing the medical profession as a whole and bestowing their condemnation on the 300 vivisectors. But the 40,000 practitioners would decline to be thus separated from their brethren engaged in research, and would stand shoulder to shoulder and show every sympathy with men whose great work had been and continues to be of incalculable service to medical science and to suffering humanity. Harvey, if he could see, would be amazed at the extent and thoroughness of the manner in which his exhortation to search out the secrets of nature is being carried into effect at the present day. The older universities have been roused into activity, and independent laboratories for pathological work established in various parts of the world. Investigators should strive after truth alone, and not merely try to gain popularity or take up research as an amusing occupation. The men engaged in this work were not all vivisectors. A great debt of gratitude was owing to those who had investigated malaria; their devoted labors were carried out under circumstances involving severe trials and great personal danger, often, indeed, leading to the loss of health and even life. Some there were who had actually risked and lost their lives by what they had undertaken as personal experiments.

Another of Harvey's exhortations was that medical men should live in a state of brotherly love, respect, and esteem, and Dr. Roberts said they might congratulate themselves on the spirit of good-fellowship prevailing among members of the colleges of physicians and surgeons.

After the oration the president, Sir D. Powell, presented the Bissett-Hawkins memorial medal to Sir Patrick Manson for the services he has rendered to science and humanity by its researches on tropical diseases. This gold medal is bestowed triennially on a British medical practitioner, who has during the preceding ten years done such work in advancing sanitary science, or in promoting public health, as in the opinion of the college deserves special recognition.

The Baly gold medal, which has been awarded to Professor Pavlov, of St. Petersburg, was then handed to the registrar to forward to him. This medal is awarded biennially, on the recommendation of the president and council, to the person deemed to have most distinguished himself in physiology, especially during the preceding two years. It is not restricted to British subjects.

The Royal Institute of Public Health yesterday had the privilege of hearing an address by Colonel David Bruce on "Sleeping Sickness." He said in some parts of Uganda, where the disease prevailed between 1896 and 1901, it in a short time reduced a populous and richly cultivated country to a wilderness. He considered it essentially a disturbance of the brain functions, and said a patient might go about his ordinary occupations for years without his friends noticing anything the matter. But gradually a slight change of demeanor would become evident, he would be less inclined to exert himself, would lie about in the daytime, and at length his intimates would be convinced that his conduct was due to the onset of the disease. Colonel Bruce's investigations led him to believe that the disease was brought to Uganda from the Congo, and that it was caused by a protozoal parasite, the infection being carried by a species of tsetse fly. Where there was no such fly there was no sleeping sickness. They had to deal with a human tsetse fly disease. This disease had a very peculiar distribution. It was restricted to the numerous islands that dot the northern part of the Victoria Nyanza and to a narrow belt of territory a few miles wide, skirting the shores of the lake, but only in localities where there was forest with high trees and dense undergrowth.

University College Hospital is obliged to come before the public with an appeal for between three and four thousand pounds to complete the new building. The sum left by Sir Blundell Maple to finish the hospital he had so munificently rebuilt has been expended, and, of course, the executors have no power to add to it, although it is as certain as such a thing can be, that Sir Blundell, had he survived, would have completed his work. The sum required for absolutely essential work is a mere trifle in comparison with what he had provided. The hospital has only about £9,000 income which can be considered reliable, and its annual expenditure exceeds £23,500, so that there is a continual deficit, and the committee are at present in great straits.

Guy's Hospital appeal has not been so successful as hoped. About £48,000 has been given toward the £100,000 asked for. Some curious facts may be interesting. Some £46,000 was given by 138 persons, their gifts ranging between £5,000 and £25. Sums under the last-named amounted to £1,000 from 220 persons. The remainder of the money received has been from the "Million Shilling Fund." Apart from the help of the press the appeal has been distributed to over 100,000 offices and homes of the well-to-do classes, besides which, the treasurer says, thousands of personal letters have been addressed to those thought likely to subscribe, and yet a direct response has been received from only 358 persons. He attributes the success of the "Million Shilling Fund" to the personal effects of the doctors, students, and nurses, and adds that it is a fact that "Guy's has been saved to the public by the generosity and endeavors of a small group of old friends." I am afraid that this is the experience of a majority of our charities. I know it is in some of them.

The Hospital for Incurables wants £2,000 urgently for current expenses. A "Shilling Fund" has been inaugurated to accomplish this, besides which a three days' bazaar has just been held; in fact, it closes this evening.

On Tuesday a convocation of Oxford University received a deputation from its medical graduates to present an address signed by 165 on the importance of providing for the teachers of pathology. The deputation was introduced by Sir W. S. Church, who said they had already collected £500 toward the establishment and endowment of a professorship. The vice-chancellor cordially welcomed the deputation, and said in due course convocation would pass a decree thanking them for their handsome assistance. He also thanked Mr. Whilley, who was present, for his liberal donation to the chair of pathology, and hoped the example of the medical graduates would find many imitators.

The Sanitary Institute visited the new Sanatorium of Frimley on Saturday. This institution has been established in connection with the Brompton Hospital in pursuance of a determination to have a convalescent home for some of the patients taken many years ago. Lack of funds prevented an earlier completion of the scheme. Sir D. Powell, president R.C.P., and others concerned met the visitors and guided them over the building. There were fifty patients in it, and there is accommodation for another fifty. Work in the open air according to strength with sanitary living and the exclusion as far as possible of damp and dust, with the free admission of air and light to the rooms, is the treatment provided. Funds are asked for, about £10,000 a year, and the governors suggest that 2,000 persons should subscribe five guineas a year each. The calculation is easy—will the 2,000 put in an appearance?

The death is reported of Dr. Herbert William Brown, at Cairo, from typhoid, on May 12. He was a London graduate, had filled resident posts at Guy's, and then done a year's earnest work at the London Tropical School, and been appointed resident to the Kaor-el-Aini Hospital. His brilliant career closes at the age of 27.

Another young life has passed in typhoid. Dr. Arthur Griffiths, of Bridgend, who was overburdened with work in an epidemic there. His wife was ill, and early one morning he went and told her nurse he was himself very ill, and he soon afterward died. He took his M.D. in 1887. He was only 34 years of age.

The senior ranks naturally furnish names to the professional roll pretty constantly. This month Dr. John Matthews, of Tynemoulle, died at the ripe age of 84. He graduated at Edinburgh in 1853. He has been retired for many years.

---

**An Accusing Tombstone.**—In a cemetery at York, Penn., is a granite monument erected to the memory of the wife of one of the residents of the place. On one side is the usual inscription; on the other is graven: "A Victim of Chloroform Poisoning and Shock, the Result of a Doctor's Negligence." The name of the doctor is not given, which is perhaps all that saves the erecter of the monument from a libel suit.

## OUR VIENNA LETTER.

(From Our Special Correspondent.)

THE SPIROCHÆTA PALLIDA IN SYPHILIS—PROGRESSIVE PARALYSIS IN A CHILD—TUBERCULOSIS OF THE TONGUE—A NEW THEORY OF PRESBYOPIA—RADICAL OPERATION IN TUBERCULOUS COXITIS.

VIENNA, June 20, 1905.

THE subject that is at present being most actively discussed is the etiological significance of the spirochæta pallida, which Schaudinn and Hoffman have described as the causative agent in syphilis. The observations which are being carried on in all the local clinics have so far yielded full confirmation of this view. Dr. R. Kraus, working together with Prof. Mracek, has been able to demonstrate the spirochæta regularly in syphilitic papules and also in syphilitic lymph glands. Control observations have shown that the parasites are not to be found in cutaneous lesions not of syphilitic origin. The spirochæta pallida is easily to be differentiated from the harmless variety by special staining methods; Giemsa's stain being used in the dilution of one to four. Good preparations may be obtained by staining from one-half to one hour. Prof. Finger has received a grant from the Vienna Academy of Sciences in order to study the question of immunization against syphilis by means of experiments on monkeys. Metchnikoff and Roux in Paris have successfully inoculated both anthropoid and lower monkeys, but Neisser of Breslau doubts the reliability of these results, as his own experiments have frequently been negative. Prof. Finger has made a short report to the Academy on the work which he has so far done in conjunction with Dr. K. Landersteiner. He has apparently succeeded in getting good results even with the lower monkeys, as out of thirty-nine inoculations only three were failures. No success has as yet met the efforts to produce immunity by inoculation with syphilitic serum, but the experiments are being continued.

Dr. Zappert has observed a case of progressive paralysis in a child six years old. Up to last year the child was in full possession of its faculties, and could not only speak well, but was intelligent in every way. During the past year rapidly increasing dementia developed, and now has reached a very marked degree. The child has entirely lost the power of responding when addressed, has forgotten how to talk, and shows no interest in her environment. When left to herself she wanders about the room and touches objects without evincing any understanding of their nature or purpose. The tongue is frequently protruded, and the lips make chewing, rolling movements. The child does not pay attention when spoken to, and objects vigorously to physical examination. There is great relaxation of the muscles of expression, the pupils are unequal and do not react to light, the patellar reflexes are exaggerated. All these symptoms, especially the rapidly progressive imbecility and the insensitive pupils afford positive evidence of the diagnosis of an infantile progressive paralysis. Syphilis, which can invariably be assumed in such cases, has not been proved present in this instance, which probably is the earliest one yet described.

Dr. Hanszel has been treating a case of tuberculosis of the tongue, which he has had under observation for ten years. The patient is eighty-five years old, and the formerly sluggish lupoid process suddenly became active after an attack of influenza, so that the tongue is now markedly swollen, and presents numerous ulcers and miliary tubercles. The patient's nutrition is greatly impaired on this account, and he is now in great danger. During the ten years' course of the affection, ulcers would from time to time appear on the dorsum of the tongue, together with more or less reactionary swelling, and after scraping and cauterization with lactic acid or silver nitrate would heal up again in the course of a few weeks. There is no evidence of tuberculosis either in the lungs or elsewhere in the body, and examinations of the sputum have always been negative. Possibly the process might be favorably affected by sunlight.

Dr. Stransky of Prague has presented a new theory as to the nature of presbyopia. The human sclera constantly increases in rigidity, partly during youth through increase in its density and thickness, and partly in age through the deposit of lime salts and decrease of elastic elements. This increasing rigidity involves an approach in form of the stretched sclera to that of the resting sclera, and shortens the bulbar radii by about 3 mm. at the age of seventy. In this way the supporting apparatus of the lens becomes modified, and from year to year the lens becomes more distorted. What it gains in refractive power, however, through the scleral relaxation it loses through its own progressive sclerosis, and therefore no increase in refractive power results. The altered form of the lens involves a successive decrease in latitude of accommodation because the difference in form between the maximal accommodating and the non-accommodating lens is constantly diminishing.

Dr. Joseph Winter has carried out interesting experiments on the effect of adrenal extract on the chloroformed heart. A 1-1,000 chloroform solution was run through the coronary arteries of a mamalian heart until it ceased to beat, and it was found that active contractions were set up again when the chloroform solution was replaced by suprarenin solution of the same strength. Cats were chloroformed until the heart action and respiration ceased, and then by injecting suprarenin solution into the left heart under artificial respiration the heart could be brought into action again, though other methods, such as cardiac massage, were ineffectual. The blood pressure in these cases would gradually rise, and finally breathing would become spontaneous. The suprarenin solution was injected either into the exposed heart or through the chest wall by means of a hypodermic syringe. Intravenous injections of suprarenin were without effect. Winter accordingly recommends in cases of chloroform collapse in which other measures are unsuccessful, the injection of suprarenin solution directly into the left heart, while at the same time active artificial respiration is kept up.

Prof. v. Mosetig-Moorhof recently spoke before the Society of Physicians in favor of radical operation in tuberculous coxitis. He employs the following procedure. Through a U-shaped incision running across the trochanter major and with its parallel portions in the direction of the fibers of the glutei the upper part of the trochanter major is resected and the joint made accessible. The capsule is then cut across and extirpated, and all diseased tissues in the neighborhood are removed, resulting bone cavities being closed with iodoform filling. The joint cavity itself must be explored for disease foci, and if necessary the head and neck of the femur are resected as well as part of the acetabulm, to which the sawn surface is fitted. In the operation the transverse pelvic muscles must be preserved intact, as they contribute to the fixation of the joint.

## Progress of Medical Science.

*New York Medical Journal, July* 8, 1905.

**Symptomatology of Acute Otitis in Children.**—C. G. Kerley gives his personal experience in seventy-two cases. The only symptom common to all was elevation of temperature. The disease was apparently primary in three. In one, it followed German measles; in two, scarlatina; in seven, measles, and in fifty-eight, grippe or catarrhal colds. In the cases in which the otitis followed, or was not immediately associated with any of the preceding diseases, which was the case in the majority, there was no special temperature characteristic of the temperature range. In some there was the morning drop and the evening rise. With but few exceptions the otitis developed during the convalescence of an acute process elsewhere; and the ear involvement was suspected because of a persistent elevation of the temperature for which no other cause could be discovered. In fifty of the cases there was absence of pain or localized signs by manipulation. The author is, therefore, inclined to believe that evidences of pain are not to be looked upon as a *sine qua non* in this disease as it affects children, but that special importance should be given to a temperature which persists without apparent cause. If a patient is restless, sleeps poorly, and evidences bodily discomfort, and examination reveals a bulging ear drum membrane, it is fair to assume from the relief following its puncture that the source of the discomfort has been discovered. The author's main contention is evident in his closing statement that we have not completed our examination of sick children until there has been a thorough examination of the condition of the middle ear.

**The Early Detection of Uterine Carcinoma.**—D. H. Craig refers to his previous article relative to the proper time for the repair of cervical lacerations, stating that in the investigation on which it was based, he was unable to find evidence of a single case of cervical carcinoma originating in a uterus in which a lacerated cervix had been successfully repaired without a subsequent trauma. He is emphatic in the assertion that there is no characteristic first or early symptom of uterine carcinoma of either cervix or body. He made a careful study of the history of 78 cases of uterine cancer, finding the first symptom to be a non-characteristic leucorrhea in 45; hemorrhage in varying degree in 21, and pain, preceding both leucorrhea and bleeding (often by many weeks) in 12. He urges upon gynecologists the imperative necessity of making a thorough physical exploration of the pelvis, both bimanually and with the speculum, of every woman who has pelvic symptoms. Great care should be exercised in securing suspected pathological tissue for the miscroscope. Manipulation of the marginal area of malignant tissue, and, much more the excision of a wedge-shaped piece increase the danger of dissemination and the patient's consent to immediate radical intervention should be previously secured in view of the possibly unfavorable showing by the miscroscope. Patients should be taught

that a foul discharge is not the only positive sign of malignancy, and that a departure from the normal onset of the menopause is in itself suspicious. Irregular flowings must be carefully investigated and their significance interpreted in the light of the findings by local examination.

*Medical News, July* 8, 1905.

**Syphilis of the Liver, Sclerogummatous Type.**—J. Funke reviews the literature of this subject, his paper being mainly a compilation of the views of various authors. The autopsy findings are given in one personal case. The liver was firm, and scattered over its external surface were subcapsular nodules, extending into the parenchyma of the organ, so far as could be determined, to a distance of about 2 to 4 mm. The organ was found to resist the knife and the cut surface was studded with nodules similar to those described as being present under the capsule. They resembled miliary tubercules in every respect, although it was quite impossible to remove what appeared to be caseous centers. The peripheries of many of the lobules were easily outlined and were slightly depressed; the depressed parts were grayish-white in color and resembled fibrous tissue. The greenish tinge was more pronounced on the cut surface than upon the external portion of the organ, giving the parenchyma a granular appearance. Near the transverse fissure of the organ was a fibrous mass having a dimension of 1 by 2 cm., which incorporated the bile passages, but did not impinge upon the vessels. A probe introduced at the ampulla of Vater would extend a far as the juncture of the hepatic and cystic ducts, where it met with an obstruction and upon dissection of the common duct the lumen was found occluded by the fibrous mass already mentioned. Upon further dissection the cystic duct also was occluded; the right hepatic could not be traced, but the left branch passed near the margin of the fibrous mass. The fibrous nodule extended into the liver for a distance of 1 cm. At no point in the growth could either duct or liver substance be identified, apparently it was fibrous throughout and distinctly circumscribed. The liver was alherent to the gallbladder, the walls of which were extremely thin.

**Some Observations on the Relations of the Gastrointestinal Tract to Nervous and Mental Diseases.**—R. C. Kemp reviews the teachings of modern physiology covering digestion and the general effect of its impairment upon the nervous system. He considers that epileptiform attacks are directly connected with putrefactive bowel states, and that ptosis of the gastrointestinal tract is a powerful factor in the production of many nervous disorders. Thirteen cases of dementia paralytica are studied in some detail, and the histories show the dimensions in the frequency of convulsions, and the lowering of the temperature which followed the regulation of the bowels and treatment of the gastrointestinal tract, according to the individual requirements. Surgery may assist many of the cases in which simple internal treatment fails. The article closes with a description of the methods followed in the care of these cases at the Manhattan State Hospital on Ward's Island.

*American Medicine, July* 8, 1905.

**Apparently Unavoidable Errors in Diagnosis of Psoas Abscess.**—H. Augustus Wilson cites enough instances to show that the diagnosis of psoas abscess is not always easy, and that each case is worthy of the most careful study in every phase presented. The presence of well-marked evidence of spinal caries is sometimes misleading. Great spinal deformity is often present long after the activity of the bone disease has subsided. When conditions more or less closely resembling psoas abscess are also present, the preponderance of evidence is often in favor of psoas abscess when in reality some other disease or condition is present. The knowledge that these errors in diagnosis have occurred under the most critical inspection and elaborate study is convincing that while they are not always avoidable, they should be guarded against as far as possible.

**Treatment of Some Neuralgias by the Röntgen Ray.**—Charles Lester Leonard calls attention to what has been accomplished in relieving intolerable conditions of pain by the use of this agent. The cases which he reports indicate what may be accomplished under favorable conditions, and are not to be taken as a definite measure of an agent with which a measured dose can be applied to accomplish the same result. Each patient and his or her disease, modified by the reaction of the Röntgen ray, must form the individual basis for treatment in each case. So far, no generalizations can be made, nor can definite results be promised. They depend upon the reaction of the patient and the adaptation to each case of the quality of ray necessary to it. Dr. Leonard reports as apparently cured cases of tic douloureux, chronic migraine, and facial neuralgia. These were chronic cases and had remained free from pain from one to two years after treatment. In one or two cases palliative results alone were observed. He concluded that although these few cases are possibly too few and of too short standing from which to deduce any valuable conclusions, they at least demonstrate that in certain conditions of intolerable pain this agent can relieve and produce apparent cures that persist for a considerable length of time. Although it cannot be stated definitely what particular classes of cases will be benefited, there is at least a prospect of temporary relief for all, and a probability that a further development of technic will increase the number of cases in which permanent results can be secured. Neuralgias are not the only painful conditions that can be relieved by this agent, for articular pain, as seen in gout and rheumatism, even after deformity and stiffening has taken place, can in many cases be permanently relieved, while the pain can certainly be decreased.

**Fibromyoma of the Corpus Uteri Coexisting with Squamous Epithelioma of the Cervix.**—B. F. Baer reports a case in which this rare combination occurred. The patient was a mulatto of 41, in whom a diagnosis of uterine fibroid had been made. Upon vaginal examination, however, the cervix uteri was found greatly hypertrophied, roughened, fissured, and with other evidences of malignant change. Under proper treatment the patient's improvement became such that Dr. Baer decided to operate. Only a high amputation was advisable at this time, and even this was rendered most difficult because of the unyielding attachments. Improvement was so rapid after operation, and her general condition so much better that two weeks later she was prepared for abdominal hysterectomy. This proved extremely difficult owing to the firmness and fixation of the surrounding tissues which entirely prevented elevation of the parts. After removal was completed the vaginal raw surfaces were thoroughly cauterized with the Paquelin cautery, and the pelvis closed in the ordinary manner. The patient made an uneventful recovery.

**Traumatic Cerebral Diabetes.**—M. J. Siefert reports a case in a boy of 16 who fell down a 12 feet elevator shaft, striking the floor head first, excoriating the skin over the right frontal and molar regions. He was unconscious 1 hour, stupefied 72 hours. Uranalysis made in less than 12 hours after the accident, showed: Sp. gr. 1.036; sugar, albumin, and blood present. Daily analysis revealed the presence of sugar for 11 days longer. Patient took an easy job 60 days after injury, remaining at work for almost two years. Then the gradually increasing debility, emaciation, polyuria, and depression of spirits induced him to seek medical advice. At that time there was a daily output of between 7 and 30 pints of urine, and sugar varied from a trace to 7 per cent. In spite of all therapeutic measures the prognosis is becoming graver from day to day. The patient is now nearly 20 years of age, and in a deplorable physical condition.

*Journal of the American Medical Association, July* 8, 1905.

**Ainhum.**—A case of this disease, rarely seen outside the tropics and usually occurring in negroes, is reported by N. D. Brayton of Indianapolis. Though so rare in the United States it is so common in India that Crawford found a case in every two thousand surgical patients in Indian hospitals. The absence of pain or inconvenience in many cases also probably prevents their being reported, especially as the patients are not of a class that ordinarily call for the surgeon's assistance. The ultimate result of the disease, which begins as a crack or fissure, is the spontaneous amputation of one or more fingers or toes by a gradual circular strangulation. In Brayton's case, complete amputation of one toe and partial amputation of another had occurred before the patient sought medical assistance or appreciated his condition. It is rare in females, and is almost exclusively confined to the dark-skinned races, only four cases having been reported in whites. Brayton thinks it probably a trophoneurosis of unknown origin. It is certainly not a form of leprosy as some have considered it. The diagnosis of the disorder is discussed. The principal conditions with which it is liable to be confounded are Raynaud's disease and mutilating leprosy. In the former, we have pain and preliminary lesions, such as bullæ and constitutional disturbance. Local lesions also occur in leprosy, but the disease is not likely to be so localized on a certain toe as in ainhum. Paronychia and neurotic ulcer have characteristic symptoms differing from those of this disorder. The treatment is usually unsatisfactory. The cases come too late. If seen early enough, linear incision, curettage, and scarification or incision of the constricting band is indicated, but does not prevent a recurrence. When the condition is of long standing or troublesome amputation is advisable.

**Transmission of Disease by Mosquitos.**—J. R. Taylor gives a good summary of the facts in regard to the transmission of disease by mosquitos, so far as known. He does not consider any of the possible methods practicable for the complete extermination of malaria, but thinks that the disease can be greatly reduced in prevalence. As regards yellow fever, he believes the methods instituted by Gorgas in Cuba, if thoroughly carried out, would exterminate the disease. The same methods will apply for the extermina-

tion, or at least the diminution of filariasis. He believes in quarantine in all possible cases of transmission of disease by vessels, that is, a quarantine based on the natural history of the disease as we know it. The isolation of infected persons is essential. For the destruction of mosquitos, sulphur fumigation is most effectual, but has its inconveniences. The powdered leaves of datura (Jimson weed) mixed with saltpeter and burned, an ounce of the mixture to each two hundred cubic feet of space, is a cheap, safe, and effective method of destroying hibernating mosquitos. Pyrethrum and formaldehyde are said to be effective against hibernating insects, though the former only stupefies the mosquitos which should be swept up and burned after its use. To exterminate the stegomyia or yellow fever mosquito, all water receptacles should be treated with oil or made inset proof, and drainage and flushing of ditches, etc., should be practised. Drainage methods are even more necessary against the malaria-bearing type which breeds especially in swamps.

**The Diagnosis of Cutaneous Syphilis.**—E. A. Fischkin concludes from his observations and studies that the elements of diagnosis in cutaneous syphilis have only an arbitrary value. The element of time is unreliable; it may happen that simple sores with consequent gland swellings will develop in intervals corresponding to the periods of syphilis. Regionary lymphadenitis is not absolutely pathognomonic of syphilis. Indolent and indurated inguinal and cubital glands may follow infection of simple wounds. The ensemble of all syphilitic symptoms may be closely imitated by non-specific dermatoses. Syphilis can only be diagnosed with absolute certainty when based on positive as well as on negative findings, *i.e.* when we not only find the characteristic elements of syphilis, but when we can with certainty exclude all other skin diseases that may appear with similar symptoms.

**Practical Significance of Certain Common Symptoms in the Upper Abdomen.**—J. F. Percy says that the upper right-hand corner of the abdomen is a field of present day investigation, which promises valuable returns for efforts to clear up its symptomatology. The most important symptom he considers is pain, and he calls attention to the various conditions which may cause pain in this region of the addomen. He also mentions the varieties of pain. He describes the different methods of percussing and palpating in order to locate the cause of the pain, and calls attention to the fact that inflammatory processes or ulcerations of the stomach may also cause pain in this region. He states that an important factor is the size of the stomach. If this organ is greatly dilated the patient may suffer for hours before obtaining relief, either by vomiting or by the use of the stomach tube to empty the stomach of the mass of undigested food, which could not be passed into the intestine. Percy relates briefly the history of some illustrative cases and concludes by saying that the internist and the surgeon must work together or the records of both in abdominal diseases will continue to be a page of regrettable failures.

*The Lancet, July* 1, 1905.

**The Influence of Atmospheric Pressure on Man.**—L. E. Hill considers the influence of diminished pressure (mountain sickness) and of increased pressure (caisson sickness and diver's palsy). The important feature in mountain sickness is not so much the loss in quantity of the oxygen in the blood as the lowering of its tension. To maintain the latter at its normal in the alveolar spaces, the mechanism of increased pulmonary ventilation comes into play. The greater the volume of tidal air, the more does the composition of the alveolar air approximate to that of the external atmosphere. A deep breather, therefore, can thus reach far higher altitudes than can a superficial breather. Training in this respect will make an enormous difference with the individual climber, who should have above all things a strong heart. Dwelling in high altitudes increases markedly the respiratory metabolism. The therapeutic effect of mountain climate depends on the purity of the air, freedom from germs and dust, strengthening of the heart and respiratory mechanism, the increased formation of hemoglobin and increased respiratory metabolism. With reference to increased pressure, it is found that the lungs after exposure to high pressure oxygen show congestion of the alveolar capillaries, hemorrhagic exudation, and consolidation. The pneumonia is patchy if quickly and universal if slowly developed. Experiments with animals as to the effects on the number of blood cells contribute but little scientific evidence to the value of oxygen inhalations in pneumonic disease. Compressed air has an effect on the circulation and the author regards all mechanical congestion theories as to the cause of caisson sickness as erroneous. The tension of the carbonic acid gas seems to have an influence on the workers in caissons quite independent of atmospheric pressure. When a tension of four per cent. is reached, dyspnea ensues, but the author adds that any factor leading to the exhaustion of the worker, such as overheated air salinated with moisture, must increase the danger of rapid decompression by lowering the efficiency of pulmonary ventilation.

**A Rational Treatment for the Elimination of Uric Acid.**—R. Fenner believes that in the light of recent research, there is a substance in the body which has such a firm combination with the uric acid that no splitting up into component parts can occur, and consequently no deposit of urates in the tissues and joints. This substance he calls "thyminic" acid. By methods described by the author, this substance can be prepared in the form of an amorphous brownish-yellow powder, soluble in cold water, slightly deliquescent, faintly acid, and almost tasteless. It is given in doses from four to eight grains after meals. He finds that in acute gout the inflammatory stage is quickly cut short and rapid convalescence induced. In chronic cases prolonged administration has been of service in nearly every instance.

**Charcot's Disease of the Ankle in a Case of General Paralysis of the Insane.**—The case reported by W. Billington and A. S. Barnes was that of a dissipated syphilitic man of thirty-seven years, who gave a history of progressive mental impairment, shooting pains and precipitate micturition. Examination revealed Argyll-Robertson pupil, signs of old hemiplegia, and some evidence of general spasticity. These, occurring in a syphilitic patient, suggest to the authors a diffuse cerebro degeneration such as characterizes general paralysis of the insane. The joint disease affected a single large articulation, came on suddenly without signs of acute inflammation, and without marked pain, and at the time when the case came under observation there was great structural change in the osseous and ligamentous components of the joint, which was much enlarged and greatly deformed, and yet was free from pain and tenderness. The chief point of interest was to determine what was the nervous disease underlying the affection of the ankle. The commonest diseases which are associated with Charcot's disease of the joints are tabes, multiple neuritis, and syringomyelia, but a careful examination of the patient sufficed to exclude the presence of these conditions. Clearly the hemiplegia was not a direct causal factor in the joint change, for the paralysis had been confined to the right side, whilst the affected joint was on the left.

*British Medical Journal, July* 1, 1905.

**Cold Affusion in Delirium Tremens.**—William Broadbent describes the treatment that he uses in cases of delirium tremens. The patient is stripped naked and lies on a blanket over a waterproof sheet. A copious supply of ice-cold water is provided, and a large bath sponge dripping with the iced water is dashed violently on the face, neck, chest, and body as rapidly as possible. He is then rubbed dry with a rough towel, and the process is repeated a second and third time. The patient is now turned over, and the wet sponge is dashed on the back of the head and down the whole length of the spine two or three times, vigorous friction with a bath towel being employed between the cold-water applications. By the time the patient is dried and made comfortable, he will be fast asleep.

**Radium Bromide in the Treatment of Rodent Ulcer.**—Alan Reeve Manby reports several cases of rodent ulcer treated by the application of a glass tube containing 5 mg. of radium bromide. He states that the effect on the tissue of the first application of the radium tube usually seems to be nil; at the second or third, marked hyperemia is apparent, and later there comes a peculiar oozing from the previously dry surface, and at this time cicatrization begins and proceeds rapidly. The cosmetic effect is excellent. Radium always maintains itself at a higher temperature than its surroundings, and gives off three different kinds of rays without any diminution of its original bulk. The combination of these rays is powerfully actinic. The little glass tube which contained the 5 mg. of radium bromide is now a rich violet color which is probably due to the action of helium on the manganese in the glass.

**Leucocythemia Treated by the X-Rays, with a Record of Four Cases.**—Charles H. Melland presents various conclusions from his study of these cases. The application of the rays was followed by improvement which was marked. The size of the spleen diminished and the condition of the blood improved. The case in which the spleen diminished most in size and in which the blood underwent the most marked improvement, was kept free from arsenical treatment. The percentage of hemoglobin and the number of red corpuscles increased as the result of treatment, while the number of leucocytes diminished. Of far greater importance, however, was the improvement in the general condition of the patients. The color improved, the weight increased, pain diminished or disappeared, the appetite came back, and a sense of well-being developed while the patients were enabld to resume their daily occupations. The writer states that with all of these encouraging signs, however, it is too soon to assert that permanent benefit has been conferred. Nevertheless, this method of treatment is followed in many cases by great amelioration in the patient's condition, and

even if eventual cure does not come, months or years of comfort may be afforded.

*Berliner klinische Wochenschrift, June* 19, 1905.

**Drowning and Means of Life Saving at the Seashore.**—Margulies, in discussing the question of the proper means of guarding against bathing accidents, analyzes the act of drowning into its different phases and degrees with those observers, such as Bronardel and Loye, who recognize five different stages. The first is that of surprise, and comprises one or two inspirations followed by expirations. This lasts from five to sixteen seconds. Then comes a period with arrested respiration, lasting about a minute, and a stage of deep respiration in which the person takes deep breaths, the eyes are open, and water is swallowed. This lasts from sixty to one hundred and fifty seconds. The fourth stage is again one of arrested respiration in which consciousness is lost and the pupils dilate. This also lasts about one minute and is followed by the last stage, which is that of the terminal respiratory efforts, occupying thirty to fifty seconds. The practical application drawn from this study of the drowning act, as well as from the author's own studies on animals, is that the prospects of saving a drowning person are very good during the first minute, not unfavorable during the second minute, but after the beginning of the third minute they grow more and more dubious. In bathing accidents the catastrophe usually comes very suddenly, so that great promptitude on the part of the life savers is necessary. Death is retarded by the fact that the body usually rises above the surface one or more times, thus giving opportunity for several breaths of fresh air, but it is hastened by any preceding muscular exercise which has led to fatigue, a feature usually present in seashore accidents. It follows that if a bather gets into danger while still near the shore, aid must reach him within one minute, a desideratum easily accomplished if the life savers are so disposed that bathers in the territory permitted to them are never at a greater distance away than can be covered in a minute. For bathers carried out by the tide efficient aid can be given only by swimming life savers to be followed by a boat, as the victim is usually incapable of making use of any ropes, buoys, etc., that may be thrown him. If a bather, fatigued by a long swim, gets into danger far from the shore, even the promptest aid is usually too late, therefore, swimming outside of a certain restricted district should be strictly forbidden.

*Münchener medizinische Wochenschrift, June* 20, 1905.

**The Action of Bichloride Injections on the Urethral Mucous Membrane, and Its Dangers.**—Asch says that the practice of self treatment of gonorrhea is still very prevalent in spite of the wide-spread efforts to disseminate a knowledge of the gravity of the condition. Bichloride of mercury is a widely used popular remedy; but its unsuitability for urethral injection is shown by five cases observed by the author. The antiseptic was used in a strength of from 1:1,000 to 1:500, and gave rise to exceedingly severe symptoms comprising swelling of the penis, a discharge of bloody serum, severe pain, and urinary obstruction due to the formation of localized patches of induration of the urethral mucous membrane giving rise to acute strictures. The author was able to confirm the presence of these latter formations by endoscopy in a case that came under his observation two days after the injection had been made. The treatment usually relieves the acute symptoms in a few days, and includes local applications of lead acetate, warm sitz baths, rest in bed, and the administration of a urinary antiseptic to prevent ascending infection of the urinary tract. Catheterization should be avoided if possible during the first days, but later on the strictures must be treated by gradual dilatation. The urethroscope may also be used in order to make local applications of iodine directly to the infiltrated areas. In conclusion, the author strongly urges the abandonment of bichloride as a urethral application in any strength, and says that oxycyanate of mercury is extremely effective as a germicide without having any irritating properties, even at a strength of 1:2,000 to 1:1,000.

**The Value of Lumbar Puncture in Otology.**—Grunert, who has used this measure as a means of diagnosis in about two hundred cases, values it very highly as a method of differentiating between ear disease alone and that simulated or complicated by meningitis. It is often impossible to tell by the ordinary clinical methods whether certain meningeal symptoms are simply secondary to the aural condition, or whether infection of the meninges has already taken place. Under the former conditions operative intervention may be life saving, but under the latter would serve only to hasten death. By the appearance of the cerebrospinal fluid obtained by lumbar puncture, it is possible to settle this point, and to determine whether or not to operate. Normally, cerebrospinal fluid should be as clear as crystal and should not differ in appearance from a similar amount of plain water held beside it, but if the least clouding is evident meningitis is already present. An otherwise apparently indicated operation should not, however, be abandoned without making a microscopical examination of the fluid, for only the demonstration of bacteria in the sediment renders the diagnosis of a diffuse purulent leptomeningitis incontestible. In two cases death followed lumbar puncture, in one because too great an amount of fluid was abstracted, while in the other, the anesthesia is supposed to have been at fault. Since then the author's punctures have always been done without anesthesia. If increased headache, dizziness, vomiting, irregularity of the pulse, twitching in the extremities, etc., are observed, it is a sign that the fluid is being withdrawn too rapidly or in too great amount, and the flow should be checked. Not more than 40 c.c. should ordinarily be removed at one session.

**A Differential Method Founded on the Occurrence of a Streptococcus in Variola and Varicella.**—De Waele and Sugg review the evidence in favor of Guarnieri's smallpox parasite, and conclude that the question of its etiological significance is still undetermined. On the other hand, they describe streptococci which they have discovered in the blood of smallpox patients, and in the pustules of cases of varicella, to which they attach considerable importance. These are non-virulent, but in each case are agglutinated only by serum coming from patients having the disease in question, and in the case of the smallpox organism, also by the serum of vaccinated persons or of calves. This agglutinating reaction is not observed with streptococci of other origin. Several cases are cited which gave results that the authors think justify them in concluding that the reaction is specific, and that by its means not only smallpox and varicella be excluded in doubtful cases, but these two affections may also be distinguished from each other.

*Deutsche medizinische Wochenschrift, June* 22, 1905.

**The Treatment of Diabetes Mellitus.**—Naunyn says that the first step in the treatment of a diabetic patient is to determine his tolerance for carbohydrates. This is done by putting him on a diet which approaches the normal, but of which the albumin and fat values are known approximately, and the carbohydrates accurately. He is kept on this for a couple of days, and from the amount of sugar excreted in comparison with that taken in the food, the tolerance is determined. In this way the patient's disease may be classified as being slight, moderate, or severe. In the latter case he should receive institutional treatment, but if his diabetes is only slight or moderate in gravity, he may be cared for at home. The next step is to cut down his carbohydrates to such a degree that all sugar disappears from the urine. He is kept down to this for at least fourteen days, and then little by little his dietary is increased until he has reached the maximum that can be allowed without giving rise to glycosuria. In managing this, it is often of great advantage, once a week or oftener, to interpolate a day of complete fasting in which only fluids are taken. In working up to the maximum diet the best way is to make each advance by allowing more milk, and if this is well borne, substituting for it a corresponding amount of some other carbohydrate. Drugs should be used only for special indications, but such accessories as baths, massage, and gymnastics may be found useful, taking care not to permit overfatigue. It is essential to have the patient keep constant watch of the amounts of all the articles of food he is consuming, and that he shall always err on the side of safety. Gaps in the dietary are to be filled with fat and not with meat or other albumins. Even with the strictest attention to diet, acidosis may result, and to guard against this, at every sugar test the Gerhardt reaction should also be carried out.

**The Treatment of Scarlatina.**—Quest abstracts the histories of 21 cases of scarlatina treated by means of anti-streptococcus serum. Eleven of the patients received Bujwid's serum, and ten were given that of Moser. The former is prepared by injecting horses with a culture obtained from a fatal case of scarlatina, and increased in virulence for rabbits by passage through animals. Moser's serum is produced by using for the injections cultures grown on bouillon, using ten to twenty different organisms in order to make the serum polyvalent. The results obtained in these twenty-one cases do not seem to indicate any very great effect on the part of the serum used. Only in a few cases was there any pronounced improvement in the general condition, the eruption was not reduced in intensity, and the inflammation of the pharyngeal organs ran the usual course. The number of published observations is still too small to permit of definite conclusions, but the author is not impressed with the value of either Bujwid's or Moser's serum.

**A New Stain for the Spirochæte Pallida.**—Reitmann says that the methods described by Schaudinn and Hoffmann have not so far rendered the detection of the spirochæta very easy for ordinary observers, and he has evolved a method which he considers more satisfactory. The cover glasses are smeared as thin as possible and are fixed for ten minutes in absolute alcohol. They are then washed in distilled water, and placed in a 2 per

cent. solution of phosphotungstic acid for five minutes. The mordant is then washed out with water and 70 per cent. alcohol, the preparation is returned to the distilled water, and then is stained with the ordinary carbolfuchsin, heated until it steams. It is then washed in tap water and placed for a moment in 70 per cent. alcohol, after which a final washing in water is made until no further color can be extracted. In such a smear the nuclei are dark, the protoplasm is light, and the spirocheta are distinctly and sharply red.

*The American Journal of the Medical Sciences, May,* 1905.

**The Action of Electrically Charged Copper upon Certain Organisms in Water.**—Mary Engle Pennington has made a trial of the action of charged copper plates on B. typhosus and B. coli communis. It was found that copper electrodes carrying a small current are actively germicidal for these organisms. B. typhosus is the more easily affected. The results of the substitution of platinum electrodes proved that it was the copper which played the important rôle. Controls in water alone, showed practically no change at the end of thirty minutes nor after one hour.

**Studies on the Bactericidal Action of Copper on Organisms in Water.**—Nathaniel Gildersleeve believes, after his investigation, that the following conclusions are warranted: Dilute solutions of copper salts have a marked destructive action on many bacteria. Of these salts the sulphate is most active. This is probably due to the fact that it undergoes electrolytic dissociation more readily than the others. The amount of sulphate to be used in the water should be from one part in 250,000 to one part in 100,000, depending upon the character of the water. Colloidal copper will quickly destroy certain bacteria; should copper vessels or plates be used to destroy bacteria in water, they must be kept highly polished or the bactericidal properties will be greatly reduced. The writer has been unable to find evidence of copper, ingested in small quantities for long periods, having a detrimental action on the health of an individual.

**A Study of the Action of Colloidal Solutions of Copper Upon Bacillus Typhosus.**—A. H. Stewart draws the following conclusions: There is a natural tendency for typhoid bacilli to die when the water containing them is allowed to stand for a long period. There may be a temporary increase in the number, but this is followed in several hours or days by a decrease and a final disappearance. Trials were made as to the period of total disappearance of typhoid organisms which had been placed in sterile Schuylkill water, and in that taken directly from the tap, and from the river surface containing large numbers of water organisms. These waters were placed in vessels of glass, porcelain, tin, and copper, and their contents, kept at room temperature, were plated every fifteen minutes for periods ranging from three to six hours. All the experiments were repeated many times. Sterile drinking water in clean copper vessels inoculated with typhoid bacilli invariably showed that the bacilli had all perished in one hour. Water similarly treated in tin vessels, invariably showed living organisms at the end of twenty-four hours. Water similarly treated in glass vessels exposed to light, showed varying results, but in no instance had the typhoid organisms all perished in three hours. Water similarly treated in enamel vessels showed a slight diminution of the number of typhoid organisms in three hours. Water similarly treated in aluminum vessels showed a disappearance of the typhoid organisms in three hours. Raw tap-water in glass vessels showed an increase in the number of organisms in three hours; occasionally there was a slight diminution in their number. Raw tap-water in copper vessels in one experiment showed a diminution from 384,000 germs per c.c. to 18,000 per c.c. in three hours. Usually, the diminution was not so great. Raw tap-water containing large numbers of river organisms and considerable vegetable matter, when inoculated with millions of typhoid organisms and placed in a copper vessel, showed that the typhoid were killed off in one and three-fourths hours to two and one-half hours. Water containing colloidal copper has a more rapid tonic action upon typhoid organisms than upon river-water organisms. The quantity of colloidal copper given off from a one-liter copper vessel in three hours was one part to four million. This amount killed off the added organisms is from one to three-fourths to two and one-half hours, and chemical experience has shown that this amount of colloidal copper is harmless when taken into the human system. In epidemics of typhoid fever, water could be purified of typhoid organisms by allowing it to stand in copper vessels for three hours.

**Purpura Hemorrhagica.**—T. W. Hastings reports a case which he considers to be an example of Werlhof's disease. The patient was an Irish boy sixteen years old. He came to the hospital complaining of weakness and inability to work. These conditions followed closely an attack of severe epistaxis which had occurred without warning, and without apparent cause. The personal history was good. Pallor was noted for the first time after the attack of epistaxis. No soreness of the mouth was complained of on admission, although for several days after the attack of epistaxis slight bleeding had continued "by spells." The gums were found on examination to be in a condition that would have accounted for a moderate amount of "blood spitting." There were at no time chills, rigor, nausea, and vomiting, or headache, which would have pointed to the onset of an acute infection. The boy had little appetite, and had lost in weight. On admission, the right tonsil was swollen. A slight sore throat was not complained of till later. The gums were soft, but only a little swollen. There was neither glandular nor splenic enlargement. From the onset of the illness there was present a purpuric eruption. The bleeding from bowels, gums, and nose was persistent . The writer declares that from the character of the lymphocytes found in the two blood examinations, leukemia seems to be excluded. The mononuclear cells were of the lymphocyte and large mononuclear types found in normal blood. The large lymphocyte with "azur-granules"—Türck's lymphoid marrow cell—was not found in this case. A post-mortem examination was not permitted.

**A Clinical and Pathological Report of a Case of Splenic Anemia.**—H. L. Sanford and David H. Dolley have had this case under their care. The patient was a man twenty-eight years old, who for a long time had suffered from anemia with gastrointestinal disturbances and pain in the splenic region. Shortly before his entrance to the hospital, the patient had had severe and repeated hemorrhages by stool and vomitus. These phenomena followed two accidents in which he had been violently thrown by a horse. Examination of the blood showed it to have the characteristics of that in secondary anemia of chlorotic type without leucocytosis. There was no general lymphatic enlargement. The patient had suffered for some time from frequent urination. Exploratory laparotomy was performed, and the spleen was found to be greatly enlarged and displaced. It was freely movable. After this operation the spleen became increased in size by almost one-half, within about ten days. At a second operation the spleen was found to be lying free in the abdomen without adhesions to the intestines or other structures. Its only attachment was a long pedicle containing four twists which were made up of large congested vessels, some of which contained thrombi. The organ was removed. The patient died seventeen days after operation. At autopsy, the liver was found to be cirrhotic. The writers in commenting on the case, state that it is impossible to decide whether or not all of the twists in the splenic veins occurred at the time of the two accidents. They believe that it is at least more reasonable to suppose that from their multiple character they did not all occur at one time, but that some had existed previously. The thrombosis of the splenic vessels, they think, must have been the cause of the sudden enlargement of the spleen while the patient was in the hospital. The lack of organization in the thrombi of the vessels removed at the time of the splenectomy proves this. The writers regard this case as one of splenic anemia associated with a cirrhosis of the liver, not as a result of the process in the spleen, but rather accompanying it. They add that the enormous elongation and torsion of the vessels associated with the dislocation of the spleen possess a very probable etiological significance in this case.

**The Clinical Aspects and Differential Diagnosis of Appendicitis and Typhoid Fever.**—Charles Greene Cumston declares that there are many cases in which these two diseases assume similar characters and are extremely difficult to distinguish one from the other. These usually represent the forms of medium intensity of both these diseases. Certain symptoms are common to both, especially pain in the right iliac fossa with or without gurgling on pressure, abdominal distention, a rise in temperature on the first day of the disease, enterocolitis and diarrhea. Rigidity of the abdominal muscles, symptoms of peritonitis, and the absence of pulmonary symptoms are in favor of a diagnosis of appendicitis. Bronchitis, severe headache, insomnia, epistaxis, rose spots after the eighth day, and hypertrophy of the spleen, point to typhoid fever. In the majority of cases, spontaneous pain is less frequent and less acute in typhoid. Intestinal gurgling on palpation of the iliac fossa has absolutely no value as a diagnostic sign. It seems probable that at least in the beginning, albuminuria will be more frequent and more pronounced in typhoid than in appendicitis. In typhoid, especially at the beginning of convalescence, there is a considerable increase in the quantity of urine, which corresponds to a discharge of extractive substances from the organism. In appendicitis, the urinary toxicity increases immediately, at the same time that the density increases and its color becomes dark. In inflammatory infections like appendicitis, especially when there is suppuration, the number of leucocytes greatly increases. In typhoid fever without inflammatory complications, the count remains normal. There may even be a hypoleucocytosis. But of all means of investigation at our command, Widal's sero-

diagnosis is the one that gives the most certain results other than the clinical symptoms. In many cases in which there is any doubt in the diagnosis between a typhoid and an abnormal appendicitis, serodiagnosis will clinch the diagnosis. In cases in which the result is positive, this sign has absolute certainty. The writer in conclusion declares that whenever appendicitis exists, either alone or associated with typhoid, operation is indicated. On the other hand, interference is contraindicated only in cases of simple typhoid, or one associated with symptoms arising from the appendix, but which are so slight that they cannot be considered as due to a true case of appendicitis.

**Some Observations on Aneurysm and Arteriosclerosis.**—C. N. B. Camac sums up his findings as follows: Arterial disease appears to be rare, almost unknown in animals. Syphilis being probably peculiar to man is by this observation placed more firmly in the list of etiological factors. Arterial disease in children under six years, even in those who are victims of congenital syphilis, is practically unknown. In those from six to fifteen years it is rare. It is found in the initial stage most commonly between the ages of thirty and forty years. The teratologic factor, though an undeterminable one, is of great importance. Arterial disease seems to be attributable to syphilis in about 32 per cent., to tuberculosis in about 16 per cent. The facts presented go to show that the colored race is affected about four times more frequently than the white. General arteriosclerosis seems to be most commonly found with aneurysm, and its presence may be considered as evidence against the probable development of aneurysm. Staining with selective stains and treating with a chemical which digests tissue shows the elastic tissue to be free of histological alterations, suggesting that this tissue undergoes physical or molecular rather than histological change.

*French and Italian Journals.*

**The Role of Alimentation in Experimental Tuberculosis.**—Richet has recently communicated to the Academy the result of the interesting experiments that he has recently made on dogs which have proved that raw meat has a very favorable influence in cases of tuberculosis, while cooked meat, on the contrary, has very unfavorable effects. In a series of dogs which he had inoculated with tuberculosis, the food given to one set was cooked meat; to another was given raw meat, and to still others was given boiled meat with rice. All of the dogs that were fed exclusively on the baked meat were dead at the end of a month; only one survived, and he had taken raw meat after a few days of the other diet. All of the dogs that had been fed with raw meat, had lived. A few dogs had been subjected to several days of fasting, they did not die, while all of the dogs which had eaten cooked meat for the same length of time had succumbed. Cooked meat produced an intoxication which completely took away the appetite in consequence of which the animals became weak and died. The experimenter simply presents the result of his reasearches without drawing any conclusion applicable to the human subject.—*Gazette des Hôpitaux Civils et Militaires,* June 13 and 15, 1905.

**Tardy Menstruation and Fecundity.**—Albert Chapotin, as a consequence of his researches in this subject, firmly believes that women whose first pregnancy is late are ordinarily those who have menstruated late. His studies included 391 cases. The delay of pregnancy is proportional to that of the first appearance of menstruation; it is also related to the irregularity, to the quantity, and to the duration of menstruation. The abundance of the loss at the menstrual period may compensate for the delay; certain women who menstruate late may have an early pregnancy if their menstruation is regular, abundant and of long duration, the quantity being the most important factor. This compensation in women who began to menstruate at the normal period, that is about 15 or 16 years of age, is habitually noted. It is more rare in women who began to menstruate very late. Sometimes it is noted that women who had their first menstruation at a time nearly normal, but irregular or slight in quantity have in a given time, it may be one child or a small number; while others who menstruated later but regularly and abundantly, have more children in the same period of time. These facts which are of so much general interest are not found in any classic treatise.—*Revue Française de Médecine et de Chirurgie,* May 20, 1905.

**Experimental Reproduction of Cancer of the Human Subject.**—Mayet suggested in 1893 that the white rat offered the most favorable soil for the experimental reproduction of cancer of the human subject. After many negative experiments on the dog, this investigator has obtained a positive result. The dog used for the experiment was in excellent condition, and he received on May 4 and May 14, 1904, respectively, 20 c.c. and 40 c.c. of the macerated tissue of a large uterine myoma which had been examined microscopically. The liquid which was filtered through a porcelain filter, did not contain any anatomical element. This animal became cachectic and died on May 18, 1905. It had a tumor of the spleen of the size of a nut; this tumor was composed of tissue of encephaloid appearance, and was composed of several masses of fusiform cells with one or two nuclei with a relatively large amount of protoplasm surrounded by a zone of embryonic cells (sarcoma). This result confirmed the author in his former theory that the liquid products of tumors can give rise far from the point of injection, to neoplasms having a cancerous structure, but which differ from that of the initial tumor.—*Gazette des Hôpitaux Civils et Militaires,* June 6, 1905.

**Fibromata of the Ovary.**—Puech, in speaking of the prognosis of these neplasms, states that they are generally of slow evolution. It must be admitted that there is a possibility of a sudden growth due to sarcomatous transformation. Every fibroma of the ovary ought to be removed even if the tumor is of small size and does not cause any trouble. Systematic intervention is justifiable on account of the uncertainty of the diagnosis, the simplicity of the operation, and its probable results. The age of the patient, the menopause, pregnancy, cachexia—none of these conditions constitutes a contraindication. Either the vaginal or the abdominal route may be employed. The results of these operations in the cases studied by the writer, have been excellent, and recurrence has never been observed.—*Revue Française de Médecine et de Chirurgie,* June 12, 1905.

**The Endovenous Use of Drugs That Have Bulbar Action.**—Luigi Ferrannini draws our attention to the fact that the endovenous use of drugs was introduced 120 years ago by Hemann. Baccelli, in 1890, introduced the endovenous use of quinine in pernicious malarial fever, on the theory that as the parasite was in the blood, the introduction of the drug directly into the blood current would counteract the activity of the protozoon. This gave most successful results. Since that time it has been used for the administration of many drugs. The author believes that it may legitimately be used for remedies that act on the nervous centers, such as strychnine and caffeine, when an immediate effect is needed. He has injected these two drugs into dogs and rabbits, and has observed the effects on the heart and respiration. Caffeine acts exclusively on the nerves of the heart and the myocardium, and raises the blood pressure, while lessening the frequency of the pulse; later the blood pressure is lowered. The author used the benzoate of sodium and caffeine, injected into the saphenous vein. The sulphate of strychnine was used in the same way. In moderate doses strychnine contracts the arteries, and acts as a bulbar excitant, the pulse being quickened, and the respiration increasing in rapidity, but not altering in rhythm.—*La Riforma Medica,* June 10, 1905.

**Bacteriolytic Action of Bile on Diplococci.**—Edmondo Berger has experimented in vitro, as well as by inoculations of animals, on the effects of bile on diplococci. It has been demonstrated that the bile not only does not act as an antiseptic to many germs, but that it even serves as a good culture medium for some of them. At the same time it has some peculiar effects on the diplococci, and it has been thought that these effects might serve as a means of differential diagnosis between the diplococci. The author concludes as follows: (1) Ox bile has a bacteriological effect on the diplococci; (2) On the typical diplococcus of Freankel the bacteriolytic action of bile is not constant; (3) This action cannot serve as a sure differential criterion between the bacillus of Fraenkel and other forms of diplococci; (4) At the same time it may serve as a means to help in the identification and differentiation of this diplococcus from the streptococcus; (5) Heat does not effect this action of the bile so as to destroy its bacteriolytic power.—*Giornale Internazionale delle Scienze Mediche,* June 15, 1905.

**Can Hernia Be Considered an Accident Due to Labor.**—Cosimo Binda discusses whether the occurrence of hernia in the course of accidents befalling laborers during the performance of their work can be considered as a true result of labor. He limits the discussion to true hernia, with a hernial sac, containing some of the abdominal contents, and a canal in the abdominal walls traversed by the hernia. It has been demonstrated by many authors that the hernia was really the result of the presence of a peritoneal sac, which may penetrate into the hernial locality, and form a canal. Most authors do not admit that a shock or pressure on one side of the abdomen may cause an instantaneous traumatic hernia. Morisani believes that when a laborer is young and strong and accustomed to hard work, and by accident he uses all the force of the abdominal muscles to resist a weight and a hernia occurs, the hernial sac may be of new formation and of traumatic origin. The author cites a case of Morisani's and one of his own to support this view.—*Gazzetta Medica Lombarda,* June 12, 1905.

---

**Mud in the Water Pipes.**—A few days ago, through the blunder of an employee, the sediment of the filter bed was pumped into the mains at the St. Louis water works in place of water from the new filter.

# Book Reviews.

Traitement des Ankyloses par la Résection Orthopédique et l'Interposition Musculaire. Par le Dr. Alphonse Huguier, Ancien Interne Lauréat des Hôpitaux de Paris (Médaille d'Argent, 1903), Ancien Aide d'Anatomie á la Faculté de Médecine. Paris: G. Steinheil, 1905.

Although this brochure contains only 140 pages, it gives a thorough résumé of the subject treated therein. The writer first points out the advantages of the use of muscle tissue in cases of ankylosis, following this with a discussion of the indications and contraindications for this treatment. In the second part of the work he considers in separate chapters the operative technique in relation to the jaw, shoulder, elbow, wrist, hip, and knee. A bibliographical index is appended.

A Textbook on the Practice of Gynecology. By W. Easterly Ashton, M.D., LL.D. Philadelphia and London: W. B. Saunders & Co., 1905.

It has been said of late that gynecology is giving up its claim to existence as one of the specialties, and some who have been prominently identified with the subject are now undertaking to allude to themselves as "abdominal surgeons." However that may be, there is still a pretty universal desire to consider the so-called diseases of women in a group by themselves and to describe them in special works. A number of the latter have lately appeared, no doubt in answer to the proper demand. Many of these are old friends in a new dress, others are entirely new and marked by an endeavor not only to present the latest advances in the science, but also to present them in a different form. Of the latter type is the recently published book by Dr. Ashton, of Philadelphia, for which a number of original features are claimed. His book is addressed to the practitioner and the student, and nothing is taken for granted in describing gynecological disease. He not only states what should be done in every case, but gives minute and explicit directions for doing it. This makes the book unusually large and marks it as a treatise rather than a textbook. The medical and surgical aspects of gynecology are each fully considered, the subject being discussed on the basis of the author's own experience, one main plan of treatment being given and then such variations as may be required in atypical cases.

The illustrations represent a departure and deserve a word of commendation. They are 1,046 in number and very extended in scope. In each operation the various steps are separately indicated and also the necessary instruments and other paraphernalia. Half-tones from photos of actual specimens or from artistic drawings are not to be found, which is quite at variance with other recent books on medical topics where elegance seemed to be the key-note which guided the illustrator. The illustrations in this book are all line drawings made under the author's personal supervision, and most satisfactory. An anatomical basis has been adopted in arranging the work, the description of the diseases of each organ being prefaced by the methods of examination employed. This has the advantage of being much less confusing than assembling them all in a single chapter. Particular attention has been paid to certain topics which are not usually considered in works of this character, among them being very detailed accounts of operations, of the repairs of visceral injuries, of the preparation and after-treatment of patients, and of the relation of appendicitis and movable kidney to diseases of the pelvic organs.

The work is essentially a "one man" book rather than a compend, and one is not left in confusion, after consulting it on any given topic, because a multitude of views have been presented.

Tuberkulose-Arbeiten aus dem Kaiserlichen Gesundheitsamte. Heft 4. S. 203. Berlin: Julius Springer, 1905.

As the title signifies, this is a compilation of the medical reports from the various sanatoria in Germany devoted to the treatment of tuberculosis. Much valuable tabulated matter is given, and plans of the structure of various institutions are included.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Opthalmology, Otology, Rhinology, Laryngology, Hygiene, and other topics of interest to Students and Practitioners. By leading members of the Medical Profession throughout the World. Edited by A. O. G. Kelly, A.M., M.D., Philadelphia, U. S. A., with the collaboration of Wm. Osler, M.D., John H. Musser, M.D., and others. Vol. I. Fifteenth Series, 1905. Philadelphia and London: J. B. Lippincott Company, 1905.

Among the interesting original articles of this issue is one on Skin Grafting in the late treatment of severe burns involving extensive areas, by Archibald Young of Glasgow. It gives the technique quite fully, and a number of pictures in illustration. Dawbarn contributes his method of cutting off blood supply to malignant growths; Durante of extirpation of the larynx. Hibbs writes on the treatment of knee-joint disease, and Gallant on that of Glenard's disease. The "Progress of Medicine" covers the field quite thoroughly, and, taken altogether, the volume is up to the average.

Hautkrankheiten bei Stoffwechsel-anomalien. Referat erstattet dem V. Internationalen Dermatologen-Kongress in Berlin (September, 1904). Von Prof. Dr. J. Jadassohn. Direktor der Dermatologischen Universitätsklinik in Bern. Berlin: August Hirschwald, 1905.

The author has based the present brochure of 122 pages upon his thema presented at the recent Berlin Congress. To the original has been added much that was not suitable for the paper and the literature of the subject from all languages has been gone into. There are no less than 462 literary references, making an addition to a work of value which renders it practically complete for future investigators.

A System of Physiologic Therapeutics. A Practical Expositon of the Methods, other than Drug-giving, useful for the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis Cohen, A.M., M.D. Professor of Clinical Medicine in Jefferson Medical College; Physician to the Jefferson Medical College Hospital, and to the Philadelphia General, Jewish, and Rush Hospitals, etc. Volume XI. Serum Therapy, by Joseph McFarland, M.D. Professor of Pathology and Bacteriology in the Medico-Chirurgical College of Philadelphia. Organotherapy, by Oliver T. Osborne, A.M., M.D. Professor of Materica Medica and Therapeutics at Yale University. Radium, Thorium, and Radioactivity, by Samuel G. Tracy, B.Sc., M.D. Radiologist, New York Skin and Cancer Hospital; Assistant Neurologist, Vanderbilt Clinic, Columbia University, New York City. Counterirritation, External Applications, Bloodletting, by Frederick A. Packard, M.D. Late Physician to the Pennsylvania Hospital. An Outline of the Principles of Therapeutics with Especial Reference to Physiologic Therapeutics, by the Editor, with Addendum on *X*-Ray Therapy, and an Index-Digest of the Complete System of Eleven Volumes. Philadelphia: P. Blakiston's Son & Co., 1905.

When the therapeutic index-digest is extracted from the sum total of pages, this volume is somewhat small (255 pages). One experiences a disappointment in the exposé of the newer methods of treatment by radiant energy, etc. Coming as this subject does at the very end of the series, it would be expected that the whole therapeutic truth would be given. But the section is far from meeting these expectations. The general index is valuable for reference to all volumes, but the impression is made of too much type and paper, where space was needed for the facts of the cae to date. Serum therapy, organotherapy, counter-irritation, all come in for a fair share, and the editor himself has written a worthy chapter on the Principles of Therapeutics.

A Nurse's Guide for the Operating Room. Second Edition, Enlarged and Revised. By Nicholas Senn, M.D., Ph.D., LL.D., C.M. Professor of Surgery Rush Medical College, in affiliation with the University of Chicago; Surgeon-in-Chief, St. Joseph's Hospital; Attending Surgeon to the Presbyterian Hospital; Professional Lecturer on Military Surgery, University of Chicago; Chief of the Operating Staff with the Army in the field during the Spanish-American War; Surgeon-General of the State of Illinois. Published under the direction of the Sisters of Charity, St. Joseph's Hospital. Chicago: W. T. Keener & Co., 1905.

In this little volume will be found all the information likely to be required by the surgical nurse. There is a complete list of the various instruments, appliances, etc., required for different operations; and there are good illustrations of most of the instruments in general use.

Surface Anatomy. By T. Gillman Moorhead, M.D., M.R.C.P.I., Physician Royal City of Dublin Hospital; Late Chief Demonstrator of Anatomy and Joint-Section in Applied Anatomy, T.C.D.; Lecturer in Medicine, Royal Sciences School, T.C.D. New York, William Wood and Company, 1905.

This capital little volume on Surface Anatomy, based on the author's lectures delivered at Trinity College, Dublin, will be found of service by physicians and surgeons. The various regions of the body are systematically gone over, and, where required, illustrations are supplied. A knowledge of deep and general descriptive anatomy is implied, being essential before the facts of surface anatomy can be appreciated. The book is well printed and illustrated, readable and valuable.

# Society Reports.

## AMERICAN MEDICAL ASSOCIATION.

*Fifty-Sixth Annual Meeting, Held in Portland, Ore., July 11, 12, 13, and 14, 1905.*

(Special Report by Telegraph to the MEDICAL RECORD.)

### HOUSE OF DELEGATES.

*First Day—Monday, July 10.*

PRESIDENT, DR. JOHN H. MUSSER OF PHILADELPHIA.

THE House was called to order at eleven o'clock, an hour after the appointed time, delay being caused by late arrival of trains, and many of the delegates were still absent at roll-call.

**The President's Address.**—Dr. JOHN H. MUSSER of Philadelphia then delivered a brief address of welcome to the delegates. He referred to the great responsibility imposed upon the delegates to whom was confided the trust of caring for the material interests of the association, leaving the members in general free to devote their whole time to the scientific work of the meeting. The task was a difficult one, but the consciousness of having fulfilled the trust imposed upon them brought its own reward, sweetening their labors and compensating for many discomforts. The president, he said, stands somewhat aloof from the permanent officers of the association, representing rather the profession at large, if it were allowable to distinguish between their interests and those of the Association. He then spoke in terms of eulogy of the permanent officers, the disinterestedness of whose labors had been questioned, and insisted that there existed nowhere more high-souled honorable men, inspired by more lofty altruistic motives, than those at present laboring so earnestly for the sole good of the organization, without a thought of self. He praised especially the excellent Secretary-Editor, who, with the assistance of the board of trustees, had done, and was doing so much to elevate the American Medical Association—what the association was to-day, it was through his faithfulness to the trust imposed upon him. The speaker praised especially the sincerity of the Secretary-Editor and of the board of trustees assisting him, but remarked that with the increasing power which was being given there was also increasing responsibility. Dr. Musser then cautioned his hearers against disregarding rules in their deliberations. The emotional impulse that often tricks large assemblies of men and drives them to foolish acts should not be suffered to carry such a deliberative body as this beyond the line of calm deliberation. This very assemblage, he said, was held against the advice of the committee on meeting-places and transportation. This exemplified the point that the general body, if it accepted the reports of its committees, should act upon them and hold the committees responsible. He spoke of the opposition that had developed against certain acts of the association, and said that this organization was able to take care of itself and foster the best interests of the profession of medicine, unmoved by outside influences. The association, he held, should represent the entire profession, and not one faction or one locality. The present organization was a recent affair, and all should remember that it might not be perfect or work smoothly at first, and when there was more or less friction they must be patient. The association was under deep obligation to the former president, Dr. Billings, for bringing the plan of organization to its present state. The speaker advised adopting the suggestion of Dr. Wyeth, one of the ex-presidents, that the determination of the place of meeting and the arrangements for the meeting be under the permanent control of the House of Delegates. He urged the members to increased efforts to promote the scientific work of the profession and raise it to a higher plane of excellence, to uphold the hands of those who were laboring in the cause of higher medical education, to bring to a clear realization the ideal of interstate reciprocity in medical licensure. At the same time, the association should not forget its duties to the nation; it should give official support to the medical men of the army, navy, and marine hospital service in their efforts to improve their respective departments. Dr. Musser then closed with a few words, congratulating the association upon the prospects of a large and enthusiastic meeting. He named the usual reference committees.

**Report of the Secretary.**—In this report it was stated that there had been 4,889 new members admitted, 938 had died or resigned, leaving a net gain in membership of 3,951. Complaint was made of the dilatoriness of the secretaries of the county societies in reporting changes in membership to the secretaries of the State societies. Dr. Simmons recommended that a card index be made of all the members of the association so that information of everything of importance regarding them could be had at a moment's notice.

**Committee Reports.**—The Rush Monument Committee reported that its labors were concluded, the monument being in place and paid for. The report was accepted and the committee discharged, with thanks for the completion of its task. The Reed Memorial Committee reported progress, and was continued. The Committee on National Incorporation presented its report in pamphlet form, the conclusions of which were read by the secretary. The discussion on this report was, on motion of Dr. Foster of Pennsylvania, deferred until the arrival of the chairman, Dr. J. D. Bryant of New York.

**Section Representation.**—Dr. E. F. Wells of Illinois offered an amendment to the by-laws that each section appoint a delegate and alternate to represent it in the House of Delegates, such appointments to be made biennially, the appointees to serve for two years. He also offered an amendment that the chairman and secretary of each section should, if deemed desirable, provide for a general lecture on some topic related to the work of the section. These amendments were referred to the proper committee for consideration and report.

**Report of the Committee on Research.**—Dr. STENGEL of Philadelphia, chairman of this committee, made a brief report, in which was recommended a grant of $100 to each of three men making important scientific researches, this grant to become permanent. It was thought this moderate sum would stimulate to work of the highest order. The report of the committee was adopted, and it was moved to request the trustees to comply with the recommendation.

The call for reports of other committees found the chairmen absent or requesting more time. Several members spoke against the plan of holding special meetings on Monday, owing to the obstruction to work caused by the absence of so many delegates and chairmen of committees.

**Report of the Committee on Legislation.**—Dr. C. A. L. REED of Ohio, chairman of this committee, had sent word that he could not attend, so the report was presented in his absence by the secretary. The report dealt with methods of influencing the political leaders of whatever party might be in power, with the status of the profession in relation to the public services, with the duties to the public of physicians in private life, with the necessity of greater independence of the sanitary authorities in the Panama Canal zone, with the pure food and pure drug questions, the whisky trust, the patent medicine trust, etc. It favored all measures looking to the improvement of the naval hospitals and the betterment of the Public Health and Marine Hospital Service, and suggested an investigation by the postal authorities regarding certain alleged medical circulars sent through the mails. It noted the scarcity of medical men in the State and National legislatures, which was regarded as detrimental to the cause of public health reform. Owing to the great expense entailed by the labors of the committee, it was suggested that a Bureau of Medical Legislation be established, with permanent offices in the Association building in Chicago; this bureau could be under the immediate control and supervision of the Secretary-Editor, some person familiar with the work being employed as assistant secretary to carry

out the orders of the chief. The report was signed by Drs. Rodman, Welch, and Reed. On motion of Dr. Wells of Illinois this report was referred to the Reference Committee.

**The Report of the Committee on the Fifteenth International Congress** followed, in which the list of papers so far as yet promised was announced. Dr. Billings moved that the report be accepted, and that $100 be allowed to defray the expenses of the committee. He also moved that the association, in union with other medical organizations, present an invitation at this congress to hold the sixteenth congress in America.

**Proprietary Remedies.**—Dr. Dorsey presented a resolution offered by the Missouri State Society regarding the present status of therapeutic preparations. The resolution, after a preamble that many remedies were in use, the composition of which was known only to the manufacturers, stated that it was the sense of the House of Delegates that the use of these remedies was reprehensible, and that the advertisements of them should not be published in medical journals. Dr. Jones of California moved the adoption of this resolution. Dr. Bacon moved an amendment that it be referred to the committee which had under advisement the report of the trustees. Dr. Harris of New York, in seconding the amendment, spoke of patent medicines as distinguished from proprietary remedies, many of which, he said, were useful. Dr. Petty of Ohio feared the reference would kill the resolution. Dr. Harris thought the wording of it was bad and could be much improved.

**The Journal and Its Advertisements.**—Dr. Philip Mills Jones Editor of the *California State Journal of Medicine*, offered a motion ordering the Editor of the *Journal of the American Medical Association* to obey the resolution adopted by the Association in 1895, which resolution required that the composition and dosage of all proprietary remedies be published with the advertisement, if the latter were accepted for insertion in the *Journal*. This resolution was referred to the same committee for consideration and report at a later meeting.

*Second Day—Tuesday, July 11, 1905.*

**Report of the Trustees.**—After the reading of the minutes of the previous session, this report was presented. In it was embodied the report of the treasurer containing a full statement of the financial affairs of the Association. It was announced with regret that the effort to get new subscribers to the *Journal* by canvassing the subordinate State and county societies, was almost a complete failure.

Dr. Eugene Smith of Detroit presented a preamble and resolution adopted by the Michigan State Medical Society in which strong objection was made against the publication by the Association of a medical directory which contained the names of irregular practitioners. For this reason the Association was requested not to purchase and republish one of the medical directories now in existence in which were to be found the names of all legally licensed practitioners of every school.

**The Report of the Council on Education** was read in part. The committee did not favor the taking of a complete college course in arts by those intending to take up the study of medicine, since the time so spent added to that devoted to purely medical studies and to hospital work would occasion unnecessary and unwise delay in entering upon practical work. It was advised that after 1908 all intending medical practitioners should be required to spend five years in study in a medical school and one in hospital practice. The appointment of Dr. George W. Webster as permanent secretary to the council was recommended.

**The Senn Medal.**—The committee on award of the Senn medal then made its report, awarding the prize to Dr. John L. Yates of Chicago. The conditions of the award were that the successful competitor should be a member of the American Medical Association who had presented the best essay on some surgical subject. The medal is of gold. Last year there were no essays presented in competition for the prize.

**The Committee on National Incorporation** reported that nothing whatever had been accomplished, and that its thanks were due to Senator McComas and to Judge Ray and his son.

**The Committee on Organization** reported a successful year's work. Opposition to the plan of medical federation had been encountered in two States.

Dr. E. E. Harris of New York offered a proposed amendment to the by-laws, placing all arrangements for meetings of the Association in the hands of the board of trustees, and providing that all the expenses of the annual meetings be met by the Association.

Dr. T. J. Happel of Tennessee offered an amendment to this amendment to the effect that the transportation committee should have the power to change the place of meeting at any time prior to three months from the date already set for such meeting.

Dr. Smith of Oregon presented resolutions endorsing the appeal of the physicians of Alaska for legislation establishing a board of medical examiners in that territory.

Dr. W. H. Sanders of Alabama moved that a committee of five be appointed to examine the present method of taking the minutes of the meetings, and to make suggestions looking to an improvement in this respect.

Dr. Smith of Oregon offered a resolution that the American Medical Association should request the National Government to give all possible aid to the Public Health and Marine-Hospital Service in its work of safeguarding the health of the country and prosecuting scientific investigation.

Dr. Harris of New York asked that, until medical union had become an established fact in his State, the present arrangement of recognizing members of either State society as in good and regular standing and eligible for membership in the American Medical Association be continued.

The reference committee were called upon for reports upon the various matters which had been referred to them for consideration, but they had no reports to make.

Dr. Wells of Illinois presented a resolution from the Section on Medicine indorsing the action of the Editor of the *Journal* and of his associates in analyzing proprietary remedies. He moved that the thanks of the Association be extended to the *Ladies' Home Journal, Collier's Weekly*, and other lay periodicals which had done efficient service in exposing the falsity of the claims of patent medicine manufacturers.

**Reports of Reference Committees.**—At the afternoon session the reports of the reference committees were presented. The secretary's request for the establishment of a Section on Electrotherapeutics was approved, the trustees were congratulated upon the increasing income of the Association and their appointment of the Council on Pharmacy was commended. The preamble and resolutions of the Missouri State Medical Society and of the Section on Medicine of the American Medical Association were approved, so also was the motion of Dr. Philip Mills Jones, calling the attention of the editor of the *Journal of the American Medical Association* to the rules of the association regarding the kind of advertisements admissible to the pages of the *Journal*.

**A National Medical Directory.**—The committee advised the publication by the association of an annual directory of all licensed practitioners in the United States, the names of those who were members of the association being indicated by special type. As a basis for this publication, the purchase of one of the existing directories was recommended. This suggestion gave rise to an animated and prolonged discussion, strong objection being made to the admission of the names of any but regular practitioners, and also to the purchase of the directory mentioned.

Dr. T. J. Happel of Tennessee quieted the discussion by stating that the Board of Trustees approved of the measure as proposed in the committee's report, and endorsed the suggestion made.

The committee further aoproved the resolution urging national support of the Public Health and Marine Hospital Service, and also the appeal of Alaska for a Board of Medical Examiners. It was recommended that the effort to secure national incorporation for the association be continued.

**Bureau of Medical Legislation.**—The recommendation of the Committees on Legislation that a permanent bureau be established in the Chicago offices of the association, under the immediate control of the secretary, was adopted. The report of the Committee on Education was also endorsed.

The Committee on Scientific Exhibit made its report, showing much work done. The report was accepted with thanks to the committee and its chairman, Dr. F. B. Wynn.

Dr. A. R. Craig, chairman of the Committee on Amendments, reported as the sense of the committee that most of the proposed amendments be rejected as of minor importance, only those shown to be of absolute necessity being recommended for passage.

Dr. E. F. Wells of Illinois offered a resolution asking that such measures be taken by the officials concerned as would prevent the excessive mortality from disease in camps during war, and also provide for better and more timely care for the injured in battle.

**Honorary Members.**—A request was presented from the Section on Pathology that F. S. Lea and M. H. Fisher of California, and G. T. Kemp of Illinois, be elected to honorary membership in the association, and from the Section on Ophthalmology that Professor Hirschberg of Berlin be made an honorary member. The Section on Pathology also suggested the passage of an amendment to the by-laws, permitting members to read two papers on different subjects in different sections, if they so desired. Amendments of similar tenor were recommended by other sections.

A recommendation, made by the International Academy of Arts and Sciences at St. Louis last summer was presented. This urged that special efforts be made to instruct general practitioners and women regarding the early signs of cancer of the uterus and of the absolute necessity of recognizing the disease in its incipiency when operation offered much greater chance of success.

**Temporary Chairman of House of Delegates.**—Dr. T. J. Happel of Tennessee offered an amendment to the by-laws to the effect that the House of Delegates elect a chairman at the beginning of each day's session in order to relieve the president of the association of the burden of presiding over the deliberations.

A resolution was presented from the Section on Stomatology, opposing the appointment of contract surgeon-dentists in the United States Army.

Dr. F. H. Wiggin of New York offered his resignation as a member of the Judicial Council. The resignation was accepted.

Dr. E. E. Harris of New York offered a resolution that the medical journals of the various State societies be instructed to unite with the Association *Journal* in its efforts to promote the purity of food and drugs.

---

GENERAL SESSION.

*First Day—Tuesday, July 11.*

Dr. John H. Musser of Philadelphia, President, in the Chair.

The Rev. A. A. Morrison of Portland opened the session with prayer.

**Addresses of Welcome** were made in behalf of the State by Judge M. C. George of the Circuit Court of Oregon, of the City of Portland by Mayor Henry Lane, M.D., of the State Medical Society by the President, Dr. George F. Wilson, and of the City and County Medical Society by the President, Dr H. W. Coe.

The Report of the Committee on Arrangements was presented by the chairman, Dr. K. A. J. Mackenzie. The President then introduced to the Association Dr. T. Hirschberg of Berlin, who was present as guest of the Section on Ophthalmology.

**President's Address.**—Dr. Lewis S. McMurtry of Louisville, Ky., the President-elect, was then introduced by Dr. Musser, and delivered his address. (See page ???.)

**Oration on Medicine.**—At the evening session Dr. Charles G. Stockton of Buffalo delivered this oration, taking as his subject, "The Delay of Old Age and the Alleviation of Senility." (See page ???.)

**Oration on Surgery.**—Dr. J. Collins Warren of Boston followed with this oration, taking as his subject, "The Surgeon and the Pathologist; A Plea for Reciprocity as Illustrated by the Consideration of the Classification and Treatment of Benign Tumors of the Breast." He introduced his exhaustive discussion of the diseases of the mammary gland by urging closer cooperation between the laboratory worker and the surgeon. The clinician and the laboratory man in these days of specialism seemed sometimes in danger of drifting further apart, and the author says that the moral to be read between the lines of his paper is concerned with this question and the necessity for some sort of a pathological "clearing house" to put things on a more practical basis. It was with this hope of inducing the clinician and the pathologist to unite and put the classification of the diseases of the breast on a more intelligible and practicable foundation that this field of surgery was selected for consideration in the present contribution. The material which served as a basis of this investigation included, in all, 758 cases of diseases of the breast; 658 cases were taken from the records of the Massachusetts General Hospital. The diseases of the male breast were purposely omitted from this table of cases, and of the total number of cases of diseases of the female breast 10 were omitted because of insufficient data to establish a diagnosis. Acute mammary abscess was also excluded from consideration. With these exceptions all cases of disease of the mammary gland were included which entered the Massachusetts General Hospital during the decade from 1895 to 1905. One hundred additional consecutive cases of disease of the breast had been obtained from the author's own private practice, making up the total of 758 cases of all varieties. Pathological reports were available in nearly every case, and in many instances the actual specimens could be obtained and were used for further study and for purposes of illustration. Four hundred and fifty-nine of the hospital cases and fifty-eight of the cases in private practice were cancer of the breast. These were included for purposes of comparison and in order better to establish the significant data for diagnosis. The greater part of the study, however, had been devoted to the benign diseases of the breast, 42 in private practice, 199 in the hospital series—a total of 241 cases of benign diseases of the breast. These were exclusive of reentries or of cases in which two diseases of different types occurred. As an illustration of the confusion in nomenclature, it was stated that in 199 cases of benign disease of the breast occurring in the Massachusetts General Hospital in ten years, 70 different pathological diagnoses appeared on the record books. The anatomy of the breast with especial regard to the formation of new growths was then discussed and the conclusion was reached that a consistent classification of tumors of the breast must take into consideration both the periductal fibrous tissue and the epithelium of the ducts, and the term "fibroepithelial" tumors suggested by Ribbert, best met these indications. Under fibroepithelial tumors of a fibrous character we might distinguish three divisions—the periductal fibroma, periductal myxoma, and periductal sarcoma. Those of the epithelial group could be divided into the fibrocystadenoma and the papillary cystadenoma. In the tumors of the fibrous group the fibrous tissue was the predominant feature of the tumor, epithelium being present, but playing only a subordinate part. In the epithelial group the fibrous tissue was present also, but merely in sufficient quantity as to be regarded as a stroma, the growth of epithelium

being the predominant feature of the tumor. The term hyperplasia was reserved for those diffuse changes not to be included among the tumors, and comprising such conditions as chronic cystic mastitis, diffuse hypertrophy, etc. The chronic inflammatory processes, as well as the non-indigenous tumors of the breast, were included in the table in order to round out the classification of all lesions except acute mammary abscess.

Classification of 758 Cases of Breast Tumor.

| | M.G.H. | Private Cases. | Total. | Per Cent. |
|---|---|---|---|---|
| Carcinoma | 459 | 58 | 517 | 68) |
| *Fibro-Epithelial Tumors* | | | (86) | (11) |
| (1) Fibrous type | | | (70) | (9) |
| 1. Periductal fibroma | 48 | 6 | 54 | 7 |
| 2. Periductal myxoma | 10 | 2 | 12 | 1.6 |
| 3. Periductal sarcoma | 4 | 0 | 4 | .5 |
| (2) Epithelial type (Cystadenoma) | | | (16) | (2) |
| 1. Fibrocystadenoma | 3 | 1 | 4 | .5 |
| 2. Papillary cystadenoma | 9 | 3 | 12 | 1.6 |
| *Hyperplasia* | | | | |
| 1. Diffuse hypertrophy | 2 | 0 | 2 | .2 |
| 2. Abnormal involution. (Cystic, 59) (Proliferative, 56) | 87 | 28 | 115 | 15 |
| *Chronic Inflammation* | | | (28) | (3.7) |
| 1. Eczema of nipple | 2 | 0 | 2 | .2 |
| 2. Chronic abscess | 5 | 0 | 5 | .6 |
| 3. Ductal mastitis | 3 | 0 | 3 | .3 |
| 4 Tuberculosis | 13 | 0 | 13 | 1.7 |
| 5. Single retention cyst | 5 | 0 | 5 | .6 |
| *Non-indigenous tumors* | | | (9) | (1.2) |
| 1. Sarcoma | 4 | 0 | 4 | .5 |
| 2. Lipoma | 3 | 1 | 4 | .8 |
| 3. Lymphangioma | 1 | 0 | 1 | .1 |
| *Supernumerary breast* | | 1 | 1 | .1 |
| | 658 | 100 | 758 | |

This table was followed by a second one to show the incidence of breast tumors by age decades, from which it was made apparent that the proportion of cancer to other tumors of the breast was a constantly increasing one to the end of life, for while between twenty and thirty years of age cancer occurred in only 6 per cent. of all cases, after seventy years the percentage was 100. The periductal fibromata were most numerous in the third decade, and constituted 50 per cent. of all tumors occurring at this time; the cyst adenomata also appeared in the third and fourth decades, with the majority in the latter, while the cyst adenomata belonged to a distinctly later period of life. Abnormal involution was most common in the fifth decade, the inflammatory processes, including tuberculosis, occurred especially in the early decades, while the non-indigenous sarcomata were found rather in the middle period of life. A large part of the very long address was then taken up by a detailed account of the pathological anatomy and clinical characteristics of each of the tumor types classified in the table.

The orator said he had given up exploratory puncture and incision on the anterior surface of the breast in cases of doubtful tumor on account of the uncertainty or disfigurement such procedures involved, and he described a conservative operation which he had used with good effect in seventy-four cases. The steps of this were as follows: The preliminary incision, starting at the lower border of the breast, opposite the middle of the outer, was in the lower inner quadrant, ran along the lower fold and outer margin to the inner border of the axilla, thus severing the lymphatic connections of the breast with the axillary plexus of lymph glands. The incision should be carried down to the lower border of the pectoralis major muscle, which should be freely exposed. The dissection was then carried along through the loose connective tissue which lay between the pectoral fascia and the posterior layer of the fascia in which the mammary gland lay. With the left hand the operator reflected the breast upward and inward so that the posterior surface of the gland became exposed in its entire length. The gland tissue could now be seen through the transparent fascia and easily inspected. If cysts were present they were readily observed, as the majority of them lay in the posterior portions of the gland. Usually there were one or two large cysts lying in the same quadrant. This portion could be removed by a V-shaped incision without opening the cysts. The apex of the V lay directly under the nipple in the central portion of the gland. Radiating from this point, incisions could be carried into the gland tissue in all directions, exposing and bisecting all small cysts so that no cyst, however small, remained that had not been laid open by the knife. A second V incision might occasionally be necessary, but this was rarely the case. The next step of the operation, after arresting hemorrhage from the larger vessels, was to close the V-shaped opening with two rows of catgut sutures, one along its anterior borders, and one bringing its posterior edges into contact. The gland was now released from the hand of the operator and dropped back on to the pectoral muscle, and it would be found that the various incised portions of the gland resumed their natural positions and fitted accurately together. A few sutures would be needed to arrest hemorrhage from small arteries in the gland substance, but this was not usually necessary. The gland should next be anchored to the subjacent pectoral muscle at its outer edge, and still another row of sutures was advisable to hold together the deep layers of the superficial fascia before closing the outer edges of the wound with silkworm gut. The buried sutures were useful in removing strain from the surface suture. The dressing should be applied so as to produce lateral compression of the two hemispheres, as the ordinary swathe tended to tear the buried gland sutures apart. If the breast operated on contained a benign tumor, the tumor could be removed by the V-shaped incision, the double suturing of the gland incision being carried out as before. It was better to make a clean V cut even in the cases of the periductal fibromata, as the capsule of these tumors was more closely adherent to the gland tissue than was usually represented to be the case. In case of exploratory operations for cancer the incision could be carried a little farther from the gland border if necessary and sufficiently deep to sever all lymphatic connections with the axillary lymphatics or those which ran through the pectoral muscle. The incision into the posterior surface of the gland, if cancer were found, should be closed by a single suture before proceeding with the major operation. This operation, the orator said, was attended with little risk or discomfort to the patient, who might be assured that it could be performed without a prolonged convalescence or disfigurement of any kind.

---

SECTION ON MEDICINE.

*First Day—Tuesday, July 11.*

Dr. Robert C. Cabot of Boston, Chairman.

**The Incidence of Heart Disease in San Francisco.**—Dr. William Fitch Cheney of San Francisco, based the study presented in this paper upon an examination of the records of 3,648 cases seen in the clinic of the Cooper Medical College during the past five years. He concluded that disease of the heart was a very common malady in San Francisco. Among the valvular troubles the form most frequently encountered was mitral regurgitation; following this was aortic regurgitation; third in the list in point of frequency was mitral stenosis; aortic stenosis came fourth, but along way after the third, being unquestionably a rare affection, at least among the dispensary patients in that city. Myocardial disease was quite commonly met with. Its etiological factors were probably the same as those supposed to lie at the foundation of arteriosclerosis; the latter condition, indeed, was even more often seen than myocarditis.

Dr. W. Ophuls of San Francisco said that he had been struck with the large number of cases of septic endocarditis which are encountered in this city.

Dr. James J. Walsh of New York likened the valves of the heart to certain joints, and said it was his belief that the heart lesions which developed during an attack of acute articular rheumatism should be regarded not as purely rheumatic in nature but as complications of the

original disease. Many of the cases now regarded as of rheumatic origin were really, he believed, septic in character.

Dr. Charles Rollins Grandy of Norfolk, Va., said his experience among the negroes of the South had been rather contrary to the usual teaching regarding the relation of rheumatism and heart disease. In his practice among this class he had found acute rheumatism to be a comparatively rare disease, while valvular diseases of the heart were common. Mitral disease was frequently encountered in those who did severe manual labor.

**The Secret Nostrum Evil.**—Dr. Frank Billings of Chicago read a paper with this title, in which he discussed the causes and the proposed remedies for this condition. The chief and most effective remedy for secrecy manifestly was publicity. No movement ever undertaken by the American Medical Association would be so far-reaching in its effects as this one which had been started to free the profession from the blight of proprietary remedies. He urged the holding of special society meetings to enlighten the profession regarding the evils of prescribing remedies of unknown composition, and advised that no one read any medical journal which contained advertisements of such remedies.

Dr. Alfred Stengel of Pennsylvania presented the following preamble and resolution: *"Whereas,* The fact that the medical profession of the United States has too long neglected to recognize the harm to the public, to the members of the profession, and to scientific medicine from the nostrum evil; and, *Whereas,* The Board of Trustees of the American Medical Association has created a body known as the Council of Pharmacy and Chemistry to investigate and pass upon the various non-official medicinal preparations placed upon the market; be it therefore, *Resolved,* That we individually and collectively heartily indorse the action of the Board of Trustees, and earnestly urge every physician to give this effort of reform his hearty support. *Resolved,* that the reporter of this section in the House of Delegates be instructed to present these preambles and resolutions to the House of Delegates, with the recommendation of this section for its indorsement, and that a copy of the same be sent to the president and secretary of each constituent society of the American Medical Association. *Resolved,* That the Board of Trustees of the *Journal* be requested to effect the removal from its pages of all advertisements of nostrums."

The resolution was discussed by Drs. John H. Musser of Philadelphia, W. G. Moore of St. Louis, Norman Bridge of Pasadena, J. T. Priestly of Des Moines, John A. Witherspoon of Nashville, Joseph M. King of Los Angeles, A. B. Grosse of San Francisco, Thomas McCleave of Berkeley, Cal.; Charles G. Stockton of Buffalo, and Carder of Victoria.

**Effects of the Inhalation of the Fumes of Nitric Acid, with Reports of Cases.**—Drs. J. N. Hall and C. E. Cooper of Denver read a paper with this title, based upon a careful study of sixteen cases. The following were the chief symptoms noted: Dyspnea, in 100 per cent.; coughs, in 93 per cent.; pain, especially in the sides of the chest, the stomach, the lungs, the loins, and the head, in 87 per cent.; dizziness and nausea, in 73 per cent.; cough of unusual violence, in 67 per cent.; vomiting, in 53 per cent. The treatment consisted in stimulation, the administration of oxygen when indicated, atropine for the edematous infiltration, vigorous counterirritation, with eliminative and supportive measures. These procedures offered the greatest hope of success in the treatment of cases seen in the early stages.

## Section on Surgery.

*First Day Tuesday, July 11.*

Dr. Maurice H. Richardson of Boston, Chairman.

**The Chairman's Address.**—Dr. Maurice H. Richardson of Boston discussed the subject of the accidents and mistakes occurring in the practice of surgery. Such unfortunate occurrences, he said, were to some extent inevitable and were bound to happen sooner or later in the practice of every surgeon. In illustration he describes a number of instances in which he himself had, through some more or less uncontrollable circumstances, been led into error, particularly in diagnosis. It was one of the difficulties of the surgeon's position that he was held responsible for every circumstance occurring during the course of a case, and he was blamed for everything going wrong, regardless of the fact that the accident or error might have taken place in such a way as to be entirely out of his control. In speaking of the education of younger surgeons, Dr. Richardson said that he believed that the most satisfactory training was that to be received under the tutelage of some experienced operator, and he urged that recent graduates should spend a number of years assisting prominent surgeons before attempting to begin practice on their own account. This method had its drawbacks, however, and if a man stayed in a subordinate position too long he might be in danger of becoming a chronic student, and so losing confidence in himself.

**The Cure of Inguinal Hernia.**—Dr. Henry O. Marcy of Boston read a paper with this title. He first discussed the history of hernia, its anatomy, and pathology. Any study of the methods of cure of hernia, he said, must involve an analysis of the predisposing and exciting causes, and this aspect of the subject was fully discussed. Coming to the matter of operation, Dr. Marcy first outlined the indications for and limitations of operation for radical cure. The fundamental problem was the reconstruction of the inguinal canal, which must be restored to its normal obliquity. In describing the details of operative technique special stress was laid on the methods of suture and the suture material, the closure of and sealing of wounds without drainage, the subsequent care of hernia patients, and the results obtained by the modern operations for radical cure.

**Fibroid Growths of the Abdominal Wall.**—Dr. Charles A. Powers of Denver in speaking of these so-called dermoid tumors referred first to their infrequency. He stated that they generally occurred in women from twenty-five to thirty-five years old, who had recently been pregnant. The growths were most often found in the region of the right rectus muscle below the umbilicus. He then discussed in detail their etiology form, size, development, pathology, and course. The symptoms, diagnosis of such conditions, and the management of the patients were then described, and Dr. Powers gave his views in the immediate and remote results of operations undertaken for their relief. Post-operative hernia and recurrence of the growths were stated to be serious considerations in deciding on the plan of treatment, and the speaker closed by giving a review of the literature of the subject, and by describing his own cases.

Dr. Robert F. Weir of New York reported having seen two cases similar to those referred to by Dr. Powers.

Dr. Rixford of San Francisco and Dr. C. Glennon of Baltimore also each reported a case of the same sort, and Dr. Connell of Fond du Lac said that he had seen two cases.

Dr. Willoughby of Los Angeles, Dr. Fulton of Astoria, and Dr. L. L. McArthur of Chicago also joined in the discussion and said that the cases reported illustrated the difficulties of diagnosis very forcibly.

The chairman, Dr. Maurice H. Richardson of Boston referred to the use of Dr. Coley's serum in such cases, and said that he had seen considerable benefit result from this treatment.

In closing the discussion, Dr. Powers said that he agreed with Dr. Richardson in regard to the value of Dr. Coley's treatment for such conditions.

**Splanchnoptosis from a Surgical Standpoint.**—Dr. Jas. E. Moore of Minneapolis read a paper on this subject in which he first referred to the many branches of medicine under which this disease might be considered. It might

be claimed as coming under the jurisdiction of several subdivisions of medical practice, but certainly surgical intervention should not be resorted to until intelligent medical treatment had been given a thorough trial, and found unavailing. He then described in detail various operative procedures by means of which he had been able to derive benefit, but he said that surgery should not be held out to these patients as a panacea because there was always a possibility that neurasthenia might persist even after its underlying mechanical defects had been repaired. Some patients were very undesirable because of the extremely stormy convalescence they made, but the immediate prognosis was good. Dr. Moore said, however, that his experience as to end results was too limited to permit him to draw very definite conclusions as to the ultimate fate of these patients.

Dr. Coffey of Oregon then showed a number of illustrations demonstrating what he had accomplished by his work along this line, one of the most important depicting the various methods in which the abdominal organs were suspended.

Dr. A. E. Gallant of New York spoke against the operative treatment of these cases, and argued in favor of postural methods. He also described a specially designed corset by means of which he had found it possible to give relief in many of these cases.

Dr. B. B. Davis of Omaha reported both good and bad results from such operations. In closing the discussion Dr. Moore said that there was not a single case on record in which it had been shown that prolapse of the liver had been caused by traumatism.

**The Early Diagnosis of Gastric Ulcer.**—Dr. H. D. Niles of Salt Lake City read a paper on this subject. He first took up the different symptoms of the affection and analyzed them according to their relative frequency. He then discussed the question of the differential diagnosis of gastric ulcer from other gastric disorders, and advised careful study and grouping of the symptoms before making a positive diagnosis and deciding on exploratory incision.

**Clinical Experiences with the Use of the McGraw Elastic Ligatnre.**—Dr. A. J. Ochsner of Chicago, in his paper on this subject, first described in detail the various steps of the operation as he ordinarily performed it. He then gave the results he had obtained by the procedure in several cases.

**Ulcer of the Stomach and the First Portion of the Duodenum with Special Reference to the Operative Treatment.**—Dr. W. J. Mayo of Rochester, Minnesota, presented an exhaustive paper with this title in which he discussed the subject from the standpoint of the operating surgeon. The first part of the paper was taken up with a discussion of the post-mortem records of gastric ulcer together with the results of the various operative procedures employed for its cure. In the clinical section of the communication he then said that two varieties of gastric ulcer might be described, the medical and the surgical, and these belonged in the province of either the physician or the surgeon. The paper closed with a detailed account of the operation of gastrojejunostomy.

The discussion that followed these papers was very animated, and Dr. Pantzer of Cincinnati said that while he admitted that the various operative procedures proposed had their indications in some cases, they were also open to serious objections, several of which he pointed out.

Dr. A. P. Francine of Philadelphia read a long list of statistics gathered principally from the records of Philadelphia hospitals and bearing on the subject of gastric ulcer.

Dr. George Goodhue of Dayton, Ohio, spoke in favor of Dr. Ochsner's method and called attention to several important advantages which procedure along these lines offered.

Dr. J. H. Carstens of Detroit spoke of the technical difficulties involved in many of these very complicated operations, and said that in order to understand such a manipulation it was essential to see it actually performed, for simply reading a printed description was wholly inadequate.

Dr. Smith of Portland, in speaking of the surgical treatment of those cases, called special attention to the Finney operation, which he said possessed numerous advantages. He also praised the Moynihan operation.

Dr. Mayo closed the discussion by speaking of the advantages and disadvantages of the Finney operation, and he also expressed himself as being much interested by the statistics gathered by Dr. Francine.

**Acid Intoxication and Late Poisonous Effects of Anesthetics.**—Dr. A. D. Bevan of Chicago, in a communication with this title, called particular attention to the effect of chloroform, used as an anesthetic, on the liver. In some instances this was exceedingly deleterious and was a not infrequent cause of death some days after anesthesia. Pathologically considered the condition was as definite an entity as acute pancreatitis or phosphorus poisoning.

Dr. Herbert C. Moffett of San Francisco said that he agreed with the views expressed by Dr. Bevan, and gave the details of six cases which he believed had died from the effects of the chloroform used as anesthetic.

Dr. Harry M. Sherman of San Francisco also referred to some cases illustrating the contentions made by Dr. Bevan.

Dr. Woods Hutchinson of Portland said that he felt that Dr. Bevan's paper would be a great aid in assisting toward the development of the new view regarding the functions of the liver.

Dr. Binswanger of Portland stated that while in the main he agreed with Dr. Bevan, yet he took issue with him in regard to the statement to the effect that the toxins found in the blood were not an essential feature of the clinical picture. On the contrary, he claimed that they were of the greatest importance, especially in such diseases as diabetes.

Dr. A. K. Steele of Chicago reported a case which he considered as being confirmatory of the statements made in Dr. Bevan's paper.

Dr. Bevan, in closing, said that he agreed with Dr. Binswanger's views on the toxins of the blood.

**Perforations in Typhoid Fever.**—Dr. Richard H. Harte of Philadelphia spoke on this complication, which he considered one of the most important features in the management of typhoid fever. He reported a number of cases, which were cited in support of his contention that taken in time perforations were susceptible of cure by surgical intervention. He therefore urged that the condition should be considered as a surgical one, and that surgeons should be called in earlier by medical men to see cases of typhoid fever.

Dr. Lawrence Litchfield of Pittsburg, in discussing this paper, asked Dr. Harte whether he advocated local or general anesthesia or the procedure of choice in operating on these cases. He also asked what had been Dr. Harte's experience as to the value of blood counts and blood pressure determinations as means of diagnosis.

Dr. Chas. A. Powers of Denver expressed himself as entirely in accord with the speaker's views and commented on the excellent results obtained by Dr. Harte in this line of work.

Dr. Manges of New York called attention to the importance of a fall in temperature and increase in perspiration as diagnostic signs in determining the occurrence of perforation.

Dr. Harte, in closing, stated that in reply to Dr. Litchfield's inquiry he would say that he preferred general anesthesia for these operations, and that he had had no experience on the question of blood pressure.

(*To be continued.*)

---

**Doyeris Cancer Sernm** possesses no curative virtues, according to the report of a committee of a French Surgical Society, which has been conducting an investigation into its merits.

## THE NEW YORK COUNTY MEDICAL ASSOCIATION.

*Stated Meeting, May 15, 1905.*

THE PRESIDENT, DR. FRANCIS J. QUINLAN, IN THE CHAIR.

**Memorial to Patrick J. Lynch, M. D.**—By Dr. FREDERICK P. HAMMOND.

**The Need of Sexual Education.**—Dr. EDWARD L. KEYES, JR., after calling attention to the frequency of syphilitic and gonorrheal infection, and emphasizing the baneful effects of those diseases, said that the promiscuous sexual congress to which they could usually be traced was largely the result of that old fable about the adult male needing intercourse for his health. Dr. Keyes said he considered promiscuous intercourse was largely a matter of habit, like smoking or drinking, though far easier to begin and far harder to break. The important point was to prevent, if possible, the young man's initial debauch, but how could this be done? One could not teach a boy morals out of a book; he would take it into a corner and make fun of it with his friends. One could not teach him out of the mouth of a woman; his innate sense of decency rebelled at that. One could not lie to him; he would find the lie out. One could not scare him much; he would not stay scared. On the other hand, one could appeal to his manliness, to his inborn sense of decency, to his sense of physical cleanliness or of religion. The appeal had to be made with authority and dignity. It should be directed, as far as possible, to that particular boy rather than to boys in general. This was only one side of the vast subject which the Society of Sanitary and Moral Prophylaxis aimed to attack. Its object was to clear up ignorance of every shade; the ignorance of the prostitute who hoped to rid herself of venereal disease by intercourse with a virgin, as well as the ignorance of the young lad who knew not how to interpret the first stirrings of sexual life; the ignorance of the man who thought he could marry within one year of his chance, as well as the ignorance of the boy who looked forward to his first gonorrhea as the portal to true manhood. The time was ripe for these things. Twenty years ago the discussion of matters sexual was considered too filthy for a medical society; to-day even the laity could take part in such discussions with a clean, intelligent interest. The clergy of every denomination were in sympathy with the movement, but it was for the medical profession to take the lead. As it was the triumph of the eighteenth century to make seduction unfashionable, and of the nineteenth to frown upon drunkenness, so it might become the glory of the twentieth to make the law of public opinion the same for man as for woman.

**Social Prophylaxis and the Medical Profession.**—Dr. PRINCE A. MORROW said he had been asked to present some observations on the character and scope of the work undertaken by the Society of Sanitary and Moral Prophylaxis, which was recently organized in this city. The object of that society, as set forth in its constitution, was the study and application of every means, sanitary, moral, and administrative, which promised to be most effective in limiting the spread of diseases growing out of the social evil. The motive for this organization lay in the fact that there existed a large and important class of diseases which constituted a grave danger to the public health, a serious menace to the health and productive energy of the family, and a powerful factor in the depopulation and degeneration of the race; furthermore, these diseases were eminently contagious, and yet entirely exempt from any semblance of sanitary control, and their existence even was ignored by those officially charged with the care of the health of the people. Venereal infection was the cause, direct or indirect, of fully one-eighth of all diseases which afflicted humanity; it invaded the domain of almost every branch of pathology; it furnished a large contingent of morbidity in the practice of the surgeon, the neurologist, the gynecologist, and the specialist in diseases of the eye, nose, throat, and other organs. Ninety per cent. of all cases of locomotor ataxia; more than 75 per cent. of all ocular paralyses; a large percentage of all cases of iritis, choroiditis and retinitis; a large but indeterminate proportion of general paralysis, paraplegia, and hemiplegia, to say nothing of lesions of the heart, liver, kidneys, and other organs, were attributable to syphilis. The disease was responsible for 48 per cent. of all abortions, and from 60 to 86 per cent. of syphilitic children dead *in utero* or shortly after birth. The pathological liabilities of gonococcus infection were scarcely less formidable. Dr. Morrow said it would be admitted that the problem of prevention was especially difficult from the exceedingly complicated character of the etiological factors. Moral and socio-economic, as well as pathological conditions, were involved. It could not be treated as a purely sanitary problem, since many of the etiological conditions lay entirely without the sphere of sanitary control. This fact, however, did not constitute a valid argument for a continuance of the present policy of entire official neglect. The evil was composite in its causes, and to correct it successfully it was necessary to have the cooperative support of the different social groups which worked for the improvement of social conditions. The Society, therefore, was intended to be composite in character, embracing in its membership medical men, representatives of the clergy, the law, public educators, sociologists, and all public-spirited citizens interested in the social welfare. Whatever might be the ultimate expansion of the Society's work, it was proposed that it should begin along the lines of education and treatment. It was generally recognized that universal elementary instruction was the most valuable of all agencies in the prevention of disease, and especially of those diseases whose causes came within the control of the individual. The prevention of venereal disease was largely a matter of personal hygiene, but it was not to be assumed that environmental conditions did not play an important rôle in their causation. The best prophylaxis was to prevent the exposure of the healthy to infection, and since the incidence of these diseases fell most heavily upon the young, elementary instruction should be particularly addressed to the rising generation. The next prophylactic indication was to prevent those infected from infecting others. In organizing a campaign of education, it was evident that physicians had to be the chief purveyors of this knowledge to the public, and in that connection it might be pertinent to inquire how thoroughly the rank and file of the profession were equipped for this educational work. In general, it might be said that popular conceptions of disease were but the reflected opinions of the medical profession. Many of the views of the laity upon venereal diseases were but the discarded opinions of the medical profession. Such, for example, was the idea, almost universally prevalent, that sexual indulgence was a physical necessity for men. Another popular error was the ignorant contempt of the danger of venereal infection. A most dangerous popular belief was that the treatment of venereal diseases required no special medical knowledge or skill; hence patients had no hesitation in entrusting their cases to the apothecary's clerk, the ignorant quack, or the merest tyro in medicine. The idea that only a modicum of medical knowledge was required for the management of venereal diseases might be traced back to its legitimate source in the low standard set by our medical schools in not demanding a knowledge of those diseases as a condition of graduation. Venereology had always occupied a subordinate position in the system of medical instruction, and even at the present day, when medical education was planned on a broader and more complete basis and a higher standard of attainments was required, it was questionable whether those diseases received the recognition their superior importance demanded.

DR. EGBERT H. GRANDIN said that while preventive medicine had made surprising advances during the past quarter century, it remained for the Society of Sanitary and Moral Prophylaxis, founded by Dr. Morrow, to impress

upon the medical profession that it had yet to fight the worst of all the scourges to which humanity was subject. It had been shown that yellow fever could be practically stamped out in localities where it had been endemic for centuries; diphtheria had lost its terrors, and the battle was on against the great white plague; yet it remained for this Society to grapple with a greater problem still, and that was the destruction of the gonococcus. Syphilis was curable, but when once the gonococcus had extended beyond the internal os of the woman, she could not be cured, so far as our present knowledge went. Dr. Grandin said that sixty-six and two-thirds per cent. of his operative work would not exist were it not for the gonococcus. Recently a great deal had been written and said on the subject of race suicide; men, it was claimed, were unwilling to procreate, and women were unwilling to bear. This was only a minor phase of the subject. The chief phase was the prevalence of gonorrheal infection. The community at large had always been kept in ignorance in regard to the importance of this subject. Sexual matters had been tabooed; gonorrhea and syphilis had been styled "private diseases" instead of foul and loathsome diseases. The fathers and mothers should first be instructed on this subject, and they, in their turn, should impart the knowledge to their children. The physician could not find a more appropriate place to begin this crusade of education than his own family. The father should instruct the boys regarding the use and misuse of the general organs; the mother, the girls. The community should be put on its guard against the men who carried these infections, and who were just as guilty and even more dangerous than the female prostitute, toward whom alone, from time immemorial, the finger of scorn had been pointed.

The Rev. Father Lavelle, Vicar-General of the Archdiocese of New York, said he was heartily in accord with the work undertaken by the Society of Sanitary and Moral Prophylaxis. In the Catholic Church the confessional brought the clergy in very close personal relation to the people, and exerted a powerful influence as a deterrent of crime. In the church with which he was connected no public instruction on sexual questions had ever been given, the idea having generally prevailed, perhaps erroneously, that such teaching would prove injurious rather than beneficial. Personally, he had been ignorant of the extent of the class of diseases under discussion; their remarkable prevalence and serious consequences were a revelation to him, and would influence his conduct in dealing with the subject in future.

Dr. Herman G. Klotz said that in his practice he had long ago become conscious of how much mischief and misery was caused by the fact that public opinion and human society ignored and refused to recognize the existence of the venereal diseases. The work of the Society founded by Dr. Morrow would necessarily be difficult, and its progress slow. The medical profession could do much to aid it and further its purposes. A very easy way to do this was to become a member of the Society, and take an active part in its work. The most important part that the medical profession could take in the combat against the venereal diseases would consist for a long time in the rapid and safe removal of all direct sources of infection by intelligent and conscientious treatment. In dealing with this class of diseases, the physician should not make light of them, nor, on the contrary, should he paint them in too dark colors. If, on the one hand, he treated them too lightly, the patient would do likewise; if, on the other hand, he treated them too seriously, the patient might become unnecessarily frightened, or consider that the importance of his trouble was exaggerated, and either neglect himself or turn to quacks. Another way in which the medical profession could promote the Society's purposes would be by influencing the administrative bodies of the private hospitals to provide accommodation for patients of both sexes affected with venereal disease. Only a few hospital beds were now available for this class of patients, and even those few were unsuitable for the majority of the patients who would appreciate them most. Special hospitals would not be advisable, on account of the unavoidable stigma that would cling to their inmates. Dr. Klotz said he was not at present in favor of the proposition of having venereal diseases reported to the health authorities, as he did not believe that such a measure would accomplish any good. It would drive patients into the hands of quacks and incompetent advisers, with disastrous results. And even if they were reported, what could the public health authorities do? It would be practically impossible to enforce isolation or quarantine in a class of diseases which, even if they could be cured, lasted often for years and perhaps a lifetime. Another effective bar to isolation would be that no island was large enough and no country wide enough to accommodate them all.

Dr. L. E. La Fétra called attention to the prevalence of gonorrhea and syphilis among children, who acquired these diseases innocently. At the Vanderbilt Clinic, where about 3,000 new patients were seen yearly, from six to ten per cent. were syphilitic patients, while from one to two per cent. suffered from gonorrheal infection, exclusive of gonorrheal infection of the eye. The speaker said he found it necessary to establish a special section in his clinic for the treatment of gonorrheal vaginitis in children. The hotbeds of this disease, which was very intractable to treatment, were the day nurseries. The disease was very contagious, traveling from one bed to another one scarcely knew how. The most important factor in the prophylaxis of the venereal diseases was the education of the parents and children. Boys and girls were naturally good; if they could be taught early in life something about sexual physiology, then the curiosity that often led them astray would be done away with. If they did not get this information from proper sources, they would get it from improper ones.

Dr. L. Bolton Bangs said the subject under discussion was such a complicated one that it was difficult to make any suggestions as to how an educational crusade should be carried out. The freedom with which the subject had been presented for discussion was certainly gratifying, and showed a wonderful and healthy advance in our ideas on sexual education. It would be difficult to overcome the ignorance of the illiterate, and the prejudice of those who still wallowed in the traditions of olden times. Each class would have to be educated along different lines, and in this work the physician could take an important part, although in so doing he would undermine, to a certain extent, his own occupation.

Dr. Edward L. Keyes said that when Dr. Morrow recently approached him regarding the formation of a society for sanitary and moral prophylaxis, he felt exceedingly skeptical about it, and to a certain extent he still felt so. The proposition was very far-reaching, and entirely at variance with our ideas of the control of other contagious diseases. Diphtheria, scarlet fever, etc., were usually acquired without any voluntary act on the part of the recipient, and were not the result of a natural sexual prompting, as was largely the case with the venereal diseases. The speaker said he was in favor of educating boys and girls along these lines. They would certainly acquire the knowledge somewhere and somehow, and it was better that they should get it from proper sources and in a proper way. Dr. Keyes said that at a recent meeting of the Society of Sanitary and Moral Prophylaxis, he had read a paper upon the subject of the sexual necessity, and he was absolutely, positively, and honestly convinced that sexual exercise was no more of a necessity for the male than for the female. No one would uphold that sexual exercise was necessary for the female, and the same could be applied to the male. The work undertaken by the Society was certainly in the right direction, and every honest and self-respecting citizen would lend his influence towards its furtherance.

Mr. Champe S. Andrews, of counsel for the Medical

Society of the County of New York, said there were many charlatans still unconvicted in this city who, through their misleading newspaper advertisements, their false methods of diagnosis, and their keeping alive and even aggravating certain symptoms, were extorting large sums of money from patients suffering from venereal diseases. Some of the more reputable newspapers and magazines now refused the advertisements of these quacks, and were even exposing their methods. Mr. Andrews said he hoped the Society, along with the rest of the work it had in view, would succeed in having a bill passed in the State of New York similar to one enacted in Michigan forbidding the newspapers to publish advertisements of this character.

Dr. Andrew H. Smith said the freedom with which this subject had been discussed was a very hopeful sign. It had formerly been surrounded by too much secrecy and mystery, which was unfortunate and should be entirely done away with.

Dr. Boleslaw Lapowski wished to emphasize the fact that gonorrhea in the male was not always a curable disease.

---

## MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

*Stated Meeting, Held May 22, 1905.*

Dr. Henry S. Stearns in the Chair.

**The Treatment of Diarrhea in Children.**—Dr. Joseph E. Winters read this paper. He said that diarrhea in children was the result of mismanagement in feeding and was a frequent cause of death, especially among young children, and it was infamous and iniquitous that such should be the case. In treating such diarrhea there were two indications, namely, removal of the cause and food adapted to the condition. Fermenting food was, as a rule, the cause of the diarrhea, and its removal was necessary. There were numerous folds in the intestines for the purpose of impeding the progression or propulsion of the food, and this made it more difficult to drive out the irritating material, such as cow's milk curds, sour milk, sausages, cheese, sauerkraut, etc., entrapped by these folds. After thrusting out the irritating material then the parts must have a period of rest, and this rest must be unquestioned and should be had until fermentation ceased to injure the irritated membrane, and all the valvular pockets healed. It was a prerequisite that during this period of transition, or period of probation, nothing be allowed to pass through the digestive tract but water; while there was any trace of disturbance food was like striking a match on a powder magazine. Castor oil was needed to get rid of the offending material. Not infrequently the irritating mass was incarcerated in a pocket, and sometimes, therefore, opium was indispensable. After the detergent action of the castor oil at the end of twenty-four hours only water should be given. Feeding while the disorder lingered was a fatal error. When there was a high temperature cold water was very grateful and was of therapeutic value. If hot water was given from a dropper, three or four drops at a time on the tongue, it would show almost a magical effect in checking vomiting. The food when about to be given must be modified and weakened; that is, the food that would be physiologically adapted for a well child of the same age must be weakened. The giving of barley water and dextrinized cereals was bad. Proteid excess was a peril to the child in summer. After clearing out the bowel with castor oil milk with its proteid content minimized was the only sure, safe, and unfailing recourse for children under one year. With regard to irrigations, he said they were overrated in the treatment of diarrhea in children. Repeated irrigations were exhausting and seldom advisable.

Dr. Arthur V. Meigs of Philadelphia opened the discussion and said that the management of diarrhea in young infants should be dietetic, for infants who nursed seldom had diarrhea; therefore, it seemed to him to indicate that the disease was largely a preventable one by the proper management of the diet. Imitating the human milk had accomplished much good. He agreed with Dr. Winters that when young infants were taken sick it was desirable to dilute the proteids, and at the same time all the other constituents of the milk should be diluted. The important thing to do was to give the infant that which was known to be the most digestible food, and a single article of diet, one that could be depended upon, was milk. It was a mistake, in his opinion, to give a child suffering from diarrhea anything except milk and, under ordinary circumstances, diluted. The cereals were poor substitutes for milk under any circumstances. Milk, the most digestible food and the only known perfect food, contained all the solids necessary for nutrition, and it did not seem to him necessary to attempt to withdraw them. Diluted milk was the sheet anchor in children suffering from diarrhea. With regard to the therapeutic management of diarrhea, particularly in young infants, he could not say how it was possible to make any distinction in the treatment when there was some irritating material in the bowel which required to be removed by purgatives. If castor oil was to be used it should be with judgment, because often this agent added fuel to the flame and had a deleterious effect unless rightly used. He preferred relying upon opium and astringents more than upon purgatives.

Dr. William H. Wells of Philadelphia did not believe that any food should be given children with diarrhea when there were acute symptoms of dyspepsia or indigestion present. He said he had had good results from a limited flushing of the intestines with the so-called normal salt solution, but he did not believe in the continuous irrigation of the intestines for long periods of time. He had been in the habit of giving castor oil as a purgative and in the dose recommended by Dr. Winters. He had also used calomel with good effect. During the early part of the attack he did not use opium, but during the later stages with stools containing mucus and blood the giving of opium would produce good results. Hypodermoclysis in many cases would save lives. He did not believe in giving large quantities of water by the mouth. He did not believe in giving cereals to children under nine months of age. Egg water and animal products in many instances were of value, but should not be too long continued. He had had good results from both the sweetened and unsweetened condensed milk.

Dr. A. D. Blackader of Montreal was unable to be present, but his paper was read by the secretary. He said that cereals could not be digested by very young children and, therefore, should not be given. When young children were afflicted with diarrhea only pure water should be given by mouth.

Dr. E. M. Buckingham of Boston said he felt that it was audacity on his part to appear before the Society to discuss the papers because he was not in accord with the gentlemen in New York on this subject. Anatomists and physiologists had taught that a child's muscles and glandular apparatus were weak, and this was one explanation why mother's milk agreed with these infants better than anything else in the way of food; if substitution was to be had for mother's milk the milk of some other animal should be given. A modified cow's milk made the nearest approach to human milk. It should be remembered that too much fat would do as much harm as too much proteid, a fact not always appreciated by pediatricists. Cereals might be used as food or as a drug. If children were fed with cereals, starch would appear in the feces, made manifest by the reaction when iodine was added, forming the blue iodide of starch. Starch was not fully digested until the child was at least one year old. What was done in the test tube was unreliable for comparison with the changes that occurred in the intestinal tract because there was no secreting surface, or any absorbing power, etc. It was astonishing how long children could go without food. In

the commencement of an attack of diarrhea it was his habit to empty the bowel at once with some oil or with calomel. It was very desirable that water should be given by the nursing bottle. If the intestines were much irritated opium in some form should be administered. He could see no value in the giving of irrigations except when used as an ordinary injection to clean out the lower bowel.

Dr. John Lovett Morse of Boston said that two years ago at the meeting of the American Medical Association he gave his opinion on this subject and had seen no reason to change it since. There were two classes of diarrhea in children, those that were bacterial and those that were not. Those that were not due to bacteria were due to causes which acted through the nervous system, such as cold, vertigo, improper food, etc., and were easily treated by the removal of the cause. The vast majority of the cases of diarrhea occurring in children were due to bacteria. The most important part of the treatment of acute diarrhea in infancy was to provide pure and fresh milk, and there would result no harm if the milk was pasteurized. As a rule the treatment of diarrhea could be divided into four stages, as follows: (1) purgation; (2) starvation; (3) feeding; and (4) drugs. The best purgative was castor oil and the next best was calomel. While it was well to wash out the stomach in the beginning, especially if vomiting was present, it was also wise to irrigate the colon once. After purgation there should be a period of starvation, but the baby should have as much water as it was accustomed to take under normal conditions, if not more. The object of this starvation was to starve out the bacteria. Personally he believed that in the majority of the cases, especially the severe cases, it was better not to begin feeding with milk, but with some substituted food. He divided the bacteria which caused diarrhea into two classes, first, those which grew on proteid foods and, second, those which grew on carbohydrates. If the stools were sour it showed the bacteria were growing on carbohydrates; if foul, the bacteria were growing on proteids. Therefore, if the stools were foul, administer carbohydrates; if sour, administer proteids. He did not believe in abstaining from food until the baby was well. In all cases the fat should be kept low. In cases of ileocolitis one should give a food that had as little residue as possible, and this was an argument against employing milk as a food under such conditions. Give whey which was absorbed high up. Opium should never be used in acute diarrhea in infancy unless there were such a large number of stools that were wearing on the child's strength. In cases of severe diarrhea serious results might happen in one of the following four ways: (1) excessive vomiting; (2) hyperpyrexia; (3) marked nervous symptoms; and (4) collapse. The elimination of the toxins might be aided by the subcutaneous employment of salt solution. Excessive vomiting might be treated by washing out of the stomach. Treat the hyperpyrexia with cold and the nervous symptoms by morphine. Collapse should be treated by stimulation and the atropia subcutaneously.

Dr. R. C. Newton of Montclair said that the nearer the baby was to the cow, when mother's milk was not to be had, the less danger was there of diarrhea happening, and in the country a fatal case of diarrhea was practically never met with. Cases in the country could not be compared with those met with in the cities, because of more sunlight, fresh air, and freedom from excitement and other disturbing influences.

Dr. John Dorning said that more could be done for these cases of diarrhea occurring in infants and young children in the first twelve hours than during the next twelve days. The bowels should be cleared out with castor oil or small doses of calomel. Absolute starvation was necessary, in his opinion, to save these children. He approved the administration of water. A child at the fourth month could digest a moderate amount of starch. During the last part of the year dextrinized starch was of value. He said that more attention should be paid to the baby, and the baby studied more carefully. What was one baby's food was another baby's poison. He did not use opiates at present. The one remedy of great value was bismuth subnitrate in large doses. A three-months-old baby could take five to ten grains; this should be repeated every three or four hours, with good results. Irrigations, he believed, had been greatly overdone. Cleanliness was very important. The value of fresh air in these diarrheas was very great.

Dr. Floyd W. Crandall referred to the adverse opinions of the gentlemen who had so far spoken in regard to the treatment of diarrheas in infants and young children. He believed that all milk should be stopped and the baby starved to a certain extent, giving barley-water. If plenty of fluid be given a baby the child could go without any food for a long time. He used dextrinized cereals. A baby with diarrhea should not be given milk. A patient with typhoid fever or appendicitis would not care to take the food, such as potatoes, beefsteaks, etc., that he was accustomed to in health; neither would a baby care to take milk when sick. In the treatment of these diarrheas it was very necessary, if a successful outcome was to be had, to begin the treatment early.

Dr. Walter Lester Carr referred to the statistics of 1903 showing the marked difference in the mortality rate among babies who were breast fed and those who were bottle fed with starchy foods, etc. He thought that all would agree that the great object to be obtained was to get a milk, or prepare the milk, in such a way that the baby could care for it.

Dr. J. Milton Mabbett referred to the conflicting views that had been expressed on the treatment of diarrheas in children and young infants.

Dr. Winters closed the discussion, and said, regarding the use of cereals, that all would arrive at the same results except that he used water with a large proportion of lime water. The laboratory results showed a slight curd when lime water was mixed with milk and the cereal. All knew the effects of lime water in causing light, loose, floculent curds. He did not mean to say that milk was harmful during the second year, but that milk with large proteid content could not be introduced without disturbing the digestive tract. Again these infants should have as much lime water as possible. What he knew regarding the proteid content of milk and the use of lime water he said he had gained from reading the letters of Dr. Meigs of Philadelphia. The fact taught by Dr. Meigs that milk contained one per cent. of proteid had been his guide in the feeding of infants, sick or well.

---

**Congenital Ulcer of Stomach, with Report of a Case.**—J. N. Hall and Thos. H. Hawkins report this interesting case. The patient was a baby girl sixty-seven hours old, well developed and of normal appearance at birth, excepting for a moderate pallor. The delivery had been normal. Within twelve hours after birth fluid regurgitated from the stomach and excoriated the right cheek and ear over which it flowed, so that they were covered on the second day with an almost continuous scab. There was no bile in this fluid. It was strongly acid to litmus paper. There was much black vomitus during the first four days. About forty-eight hours after birth a drachm or more of pure, bright red blood was thrown up from the stomach. During the second forty-eight hours this occurred on five other occasions. From the first the stools were black and tarry, evidently from old blood clots. It seems evident that hemorrhage had occurred in the alimentary tract before birth. The temperature was subnormal, the pulse was very weak, and collapse was severe. Although the abdomen was rather rigid, no especially tender point was found. The diagnosis of ulcer of the stomach was made. Treatment consisted of half-grain doses of bicarbonate of sodium with bismuth every hour. Soda was also given in the drinking water and lime water in the milk. Upon the occurrence of bleeding doses of 1/10 minim of 1:1000 solution of adrenalin were given every fifteen minutes. No hemorrhage occurred after the sixth day, and the baby is now entirely well and normal. The prognosis in such cases seems to be better in children than in adults.—*Denver Medical Times.*

**Contagious Diseases—Weekly Statement.**— Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending July 8, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 447 | 16 |
| Diphtheria and Croup | 261 | 20 |
| Scarlet Fever | 74 | ..... |
| Smallpox | ..... | ..... |
| Chickenpox | 24 | ..... |
| Tuberculosis | 305 | 167 |
| Typhoid Fever | 59 | 13 |
| Cerebrospinal Meningitis | 27 | 29 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1,187 | 245 |

**Cessation of Epilepsy Consequent on Removal of Adenoids.**—St. Clair Thomson reports this case. The patient was a girl six years old, who had been subject to fits for two years. The child had a marked adenoid facies. She was deaf, so that whispered speech was heard only at a distance of two yards. The membranæ tympani were very translucent; they were only slightly retracted, and the pink injection of the inner tympanic wall was easily visible, shining through the drum membrane. The writer notes that in children this appearance is very characteristic of eustachian and middle-ear catarrh from adenoids. With digital examination these growths were found to be plentiful in this case. There were no palatine tonsils present. The writer removed a large mass of adenoids. Within two weeks the patient had ceased to be a mouth breather. The membranæ tympani no longer looked pink, and the child heard a whisper at four yards. She was much brighter and slept quietly, but the fits continued. It was not till four years later that the writer heard again from the parents of the child. They reported that the fits had ceased within a few months of the operation and had not recurred. Her weight is sixteen pounds above the average. She has no trace of adenoids and her hearing is perfect. There is no marked arching of the hard palate. She is now nearly thirteen years of age and has had no fits for seven years. Although the writer does not claim that the patient is permanently exempt from recurrence, since relapse is said to occur after the lapse of nine years, especially at the onset of puberty, still he declares that the relief seems fairly attributable to operation. The improvement that it has wrought in the child's appearance and in her general physical and mental well-being cannot be doubted.—*The Practitioner.*

**A Possible Mode of Action of the X-Ray Upon Cancerous Growths.**—William Clifton Lyle believes that while it is possible, and, in fact, probable that there is an electrolytic action present in the use of the *x*-ray, it is a purely chemical one that exerts a curative effect. He gives as his reason for this belief the fact that there is nothing in the pathological conditions present in these growths of a malignant character to discredit an opinion that some biochemical process may be the principal factor in their etiology; and if so, any chemical measure that would tend to neutralize this action or restore proper function, would of itself effect a cure. He has observed that after a few *x*-ray exposures of such growths, even where the integument was intact, there was a more or less profuse exudate of a clear, transparent, lemon yellow fluid of a specific gravity of about 1.060, with distinctly alkaline reaction; so strongly alkaline, indeed, as to act as a caustic. This exudate crystallizes readily upon exposure to the air, and occurs in all cases of carcinoma. There is always during treatment a more or less mild form of toxemia due to absorption, the writer believes, of this product of chemical decomposition. This is especially marked in cases in which drainage is imperfect. He has noted several cases in which death has resulted from this cause, occurring in patients with malignant internal growths without external drainage. Consequently, he declares that internal growths of considerable size should never be treated by the *x*-ray unless drainage is established in some way. He suggests as the possible exception to this rule cases of inoperable cancer accompanied by intense pain. For in such instances the danger from toxic effects may be more than offset by the relief experienced.—*The Georgia Practician.*

**A New Method of Separation of the Urine by Massage.**—Drs. Giordona and Nicolich, of Triest, obtain the urine from either kidney without the use of a ureteral catheter. Giordono observed during a nephrectomy that the urine in the manipulated kidney was pressed out, so that the first urine passed after the operation contained morbid products. Following this hint, it occurred to him that the urine might be expressed for diagnostic purposes by massage. The procedure is very simple. The bladder is first emptied, and then one of the kidneys and its ureter is massaged through the lumbar and abdominal regions. The resulting urine in the bladder is withdrawn, the bladder again carefully washed, and the same process applied to the remaining kidney. A number of diagnoses arrived at by this procedure were later confirmed by nephrectomy. The simplicity of this method will commend it to physicians, owing to the fact that to catheterize a ureter, especially in the male, requires special skill, and it is a question of grave importance whether or not a catheter, after passing through an infected bladder, ought to be inserted into a healthy ureter.—*Indian Medical Record.*

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended July 8, 1905:

### THE INFLUENCE WHICH THE ACQUISITION OF TROPICAL TERRITORY BY THE UNITED STATES HAS HAD, AND IS LIKELY TO HAVE ON AMERICAN MEDICINE.*

By GEORGE BLUMER, M.D.,

SAN FRANCISCO.

It is a custom in many universities, both in this country and in Europe, to allow each professor leave of absence during every seventh year of service. This custom is doubtless based on the Sabbatical year of the Pentateuchal codes, an institution which demanded that the fields be allowed to lie fallow every seventh year. It is a question whether the Sabbatical year, as an institution, could not with benefit be introduced into matters medical, and whether we might not profit by resting every seventh year, and devoting our time, not to the strenuous throes of medical existence, but to a calm, dispassionate review of the progress of medicine in the preceding septennate, and the factors which have influenced that progress. With this idea in view I have chosen to speak to-day on an aspect of our medical progress which is now in its Sabbatical year.

It is at present almost exactly seven years since, by the terms of treaty following the Spanish War, the United States came into possession of tropical territory in both the eastern and the western hemispheres. It is unnecessary and inappropriate to discuss here the general significance of this territorial acquisition, its bearing on politics, its effect on commerce, its influence on public affairs in general; it is sufficient if we, as the representatives of the medical profession of this country, take stock of the medical questions involved, discuss their significance, and gauge the effect which they exert on American medicine in general. No doubt many of our hyperopic brethren foresaw, seven years ago, some of the effects which our acquisition of Porto Rico and the Philippines was to have on American medicine. There is just as little doubt that some of the results were entirely unlooked for, and have been complete surprises. It might appear at first sight that, from analogy, we should have been able to foretell the influence which increased commerce with our tropical territory, and the return of our soldiers and sailors with tropical diseases would have on medicine in the United States. Obviously one would look to the experience of European countries, and notably of England, to form a basis for judgment, for these countries have had tropical possessions for generations. It must not be forgotten that the physical conditions here are different from those in Europe, for while Europe is almost entirely within the temperate zone, portions of this country are semi-tropic, and a few very small areas are actually within the tropical belt. The United States, therefore, presents a much more favorable soil for the transplantation of tropical diseases than does Europe. Realizing this, numerous American writers on tropical diseases have sounded, in the last seven years, notes of warning and alarm. Their apprehensions are based more on theoretical grounds than on observed facts, but for all that are worthy of our most serious consideration. The object of this inquiry is to determine, if possible, how great this danger is. What are the prevailing diseases of our tropical possessions? Which of them, if any, has appeared among us; which, if any, has gained a foothold on our soil; and which may possibly become widely distributed? Aside from endeavoring to answer these questions, we may with profit glance at the effect which the study of tropical diseases has had on the comprehension of cognate diseases in the United States, and also observe that it has led to the recognition in this country of unsuspected diseases of wide distribution, and great economic importance.

**Uncinariasis.**—Perhaps one of the most startling results of the increased interest in tropical diseases has been the discovery that large sections of the southern portion of this country are infected with the hookworm, and that large numbers of the inhabitants are suffering from uncinariasis (ankylostomiasis) or hookworm disease. The starting point of this remarkable discovery was, almost certainly, the work of Ashford in Porto Rico in 1900. This observer noted the great frequency of the disease in that island, and pointed out that, to a large extent, the disability and wretched condition of many of the natives was due to it. The credit for drawing attention to the probability that the disease was widespread in our southern states is due to Charles Wardell Stiles, the zoologist of the Bureau of Animal Industry, and to him also is due the credit of amply proving what he at first brought forward merely as a probability. It would be out of place here to go into details as to the clinical history of this disease, or the minute structure of the parasite which causes it. Mention must be made, however, of Stiles' discovery that the American uncinaria differs from that of Europe. It will be of interest to consider the geographical distribution of uncinariasis in this country, the main facts connected with the method of its spread, and the evidence as to the likelihood that it will become more widely prevalent than it is at present.

Up to the year 1900, not more than ten authentic cases of uncinariasis were on record in American literature, though there are statements by southern physicians in the writings of the early part of the nineteenth century which leave little doubt that the disease was then prevalent. During 1900 and 1901 only nineteen cases of the disease were reported, but in 1902, following the publication of Stiles' monograph on "The Significance of the Recent American Cases of Hookworm Disease in Man," the number

*Oration on State Medicine at the Fifty-sixth annual session of the American Medical Association, Portland, Oregon, July 11-14, 1905. From advance proofs by courtesy of the *Journal of the American Medical Association*.

of reported cases rose at a bound to 524. In 1903, 273 cases were reported; in 1904, 334; the number this year will probably not be so large, as the disease is no longer a rarity to southern physicians, and they will not be so apt to record cases. Prior to 1900, then, possibly ten authentic cases of hookworm disease had been reported; since this date I have been able to collect from the available American literature 1,212 cases, of which 1,095 originated in the United States, and 117 were imported from other countries, mainly from Porto Rico and the Philippines. Of the latter, 62 are reported by Gunn, and occurred in San Francisco, mainly among Porto Ricans.

If we separate the domestic from the imported cases we find that this disease is distributed mainly through the southern states along the seaboard from Virginia to Texas. But it is not confined to the seaboard states, for Missouri and Tennessee are also infected. The states in which the disease is known to be indigenous, and probably widely distributed, are Virginia, North and South Carolina, Georgia, Alabama, Florida, Louisiana, Texas, Mississippi, Missouri, and Tennessee. This list of states includes only those in which definite evidence of the presence of the disease has been furnished; it does not include, I think, all of the infected states. Taking into account the similarities of soil and climate, any one who will take the trouble to make a map of the known infected area will feel convinced that Arkansas, Indian Territory, Oklahoma, West Virginia, Kentucky, and the southern portions of Illinois, Indiana, and Ohio are also probably infected. The physicians in some states have shown a lamentable lack of enterprise in investigating this disease, while in other states extensive and valuable studies have been made of it. As I have already stated, 1,095 cases of domestic uncinariasis have been reported since 1900, 824 of these have been observed in three states, Georgia, Alabama, and North Carolina. This has been due to the interest and energy of single physicians: in Georgia of Claude A. Smith, Warfield, and Harris; in Alabama of E. D. Bondurant, and in North Carolina of Nicholson and Rankin. A knowledge of the distribution of the disease is not merely of academic importance, for the economic aspects of uncinariasis are paramount. There is little doubt that the stigma of laziness and general inefficiency which has attached for generations to the so-called "poor whites" of the South has been earned by them not as a result of qualities due to innate "cussedness," but because a large percentage are suffering from uncinariasis with the resultant physical and mental deterioration. This being the case, a plotting out of the infected areas is one of the first steps which must be taken preparatory to stamping out the disease. This is only one step, however, the others depending on our present conception of its method of spread. At present there are two main theories as to the means by which the parasite gains entrance to the body, the one presupposing that it enters through the alimentary canal, the other that it gains entrance through the skin. The advocates of the former theory hold that polluted drinking water, and food soiled by dirty hands are the means of introduction, the advocates of the latter, that the so-called "ground itch" is the point of entrance of the *Uncinaria rhabdites*. There is a good deal of evidence in support of both views, though the work of Claude A. Smith, and that of Nicholson and Rankin favors the idea that the cutaneous form of infection is the more important. In view of this the wearing of shoes, especially during the rainy season, becomes the most important prophylactic measure, though the necessity for pure water supplies and the proper disposal of excreta still remains of great importance. In all such matters the enforcement of hygienic laws can never be obtained without education of those who are at fault. As uncinariasis is essentially a country disease (I have not been able to find on record a single American case which originated in a city), the question is one which must be dealt with by the country physician, on whose back falls a heavy load of responsibility. The stamping out of this disease is, of course, of great economic importance to the South, but, further than this, the question arises whether it may not be of importance to other parts of the country. Is there any chance that uncinariasis may become more widely distributed than it is at present? The question is a hard one to answer. While there has not been a lack of physicians who have predicted such a spread, it cannot be said that there is much actual evidence that it has occurred. There are a few instances in American literature in which the evidence plainly points to infection of natives from imported cases. Such for example, are some of the cases reported by Möhlau in Buffalo, where Polish and Italian laborers contaminated a brickyard. That such sporadic outbreaks can and will occur cannot be denied, and physicians all over the country should be on the lookout for them. Whether the disease will ever become widespread outside of its present habitat is quite another story. It must not be overlooked that a variety of circumstances are necessary for its spread: the right kind of soil, sufficient heat, and enough moisture for the parasite, and a lack of certain hygienic precautions on the part of the inhabitants of the area to be infected. The absence of any one of these conditions may be fatal to the dissemination of the disease. Considering the fact that uncinariasis has existed in the South for at least 100 years, and probably longer, it does not seem very probable that it will ever extend much beyond its present limits. What is needed at present then, is a more accurate knowledge of its distribution, and the inauguration of an educational and sanitary campaign to effect its extermination.

**Dysentery.**—One of the first diseases which the American army surgeons in the tropics had to confront was that scourge of camps, dysentery. The study of the acute form of the disease had received a great impetus from the work of Shiga in Japan, and the investigation of this condition in the American troops in the Philippines, instigated by Flexner, has since been carried on by Strong and Musgrove, J. J. Curry, and Charles H. Craig. It can fairly be said, I think, that our conception of the etiology of dysentery, and particularly of the tropical form, has been completely revised in the last few years, and this revision has depended, in no small measure, on the work of American investigators. So far as tropical dysentery is concerned, the studies of recent years have taught us to recognize two distinct forms, the bacillary and the amebic. The bacillary form, of which the acute dysentery of the tropics represents the most common type, is due to an organism first described by Flexner, and closely allied to the bacillus described by Shiga in the epidemic dysentery of Japan. In the chronic forms the ameba seems to have held its ground as the main causal agent, though the earlier investigators in the Philippines seemed inclined to think that it was usually a secondary invader. Our knowledge of the life cycle of the ameba, of the differentiation of pathogenic from non-pathogenic forms, and of the cultivation of the organism, has been achieved in the past few years, and is associated with the names of Craig, Strong and Musgrave, and Caspar Miller. A more exact knowledge of the complications of dysentery has also resulted from the

work of our army surgeons, and it is to be especially noted in this connection that the so-called "tropical" abscess of the liver is nearly always due to the amebic as opposed to the bacillary form.

The most surprising and unlooked-for result of the stimulus given to the study of dysentery has been the discovery that the same group of organisms which are responsible for tropical bacillary dysentery are also concerned in dysentery in this country, and in certain forms of the summer diarrheas of infancy. The first steps in determining these relationships were taken under Flexner's guidance during 1902. In that year Vedder and Duval published the result of their work on the dysentery of the United States, work which was based on both sporadic and epidemic cases, and which showed that certain types of dysentery all over the world were due to the Shiga group of bacteria. In the same year Duval and Bassett published their preliminary announcement of the isolation of bacteria of the same group from cases of infantile summer diarrhea. Subsequent studies, conducted mainly at the large centers in the East, have, in the main, confirmed these observations, and have led to more accurate knowledge of both the clinical and bacteriological aspects of these two classes of disease. Since 1903 investigation has been mainly focussed on the summer diarrheas of infancy, the scourge of the tenement districts of the large cities. These studies have resulted in the classification of the *Bacillus dysenteriæ* into three main types, a differentiation which was suggested in part by Gay and Duval in 1903, and which has since been rendered more exact by the work of Hiss and Russel, and that of W. H. Park and his associates. On the clinical side it has been shown that all classes of summer diarrhea are not due to organisms of the dysentery group, but that certain types marked by the presence of mucus and blood in the stools are nearly always associated with them. It has also been shown that these organisms, like the pus cocci, may give rise to primary infections, or may play the rôle of secondary or terminal invaders. Mild cases without blood in the stools may also be due to this group of organisms, accurate and early diagnosis only being possible in any type of case by means of a bacteriological examination of the feces. The serum reaction, while of some value, appears late in many cases, and is not available for early recognition of the disease.

In his report on Philippine dysentery Flexner suggests the possibility of serum therapy in these cases, and the discovery of the relation of the *Bacillus dysenteriæ* to infantile summer diarrhea led to attempts at the production of a curative serum. During 1904 such a serum was used in a number of outbreaks of dysentery and summer diarrhea. The results, as a whole, have been disappointing, but will probably improve as we gain in experience. As Booker pointed out in 1903, little is to be expected from the serum in cases in which marked anatomical lesions are present. The work done at the Rockefeller Institute and summarized by Holt shows that the serum to be of value must be used early and in repeated doses. Judging from the results of Shiga in Japan more is to be expected for the serum treatment, and, as a matter of fact, it has not yet received a fair trial in this country. At present we need more knowledge regarding the natural history of the dysentery germ, its method of introduction, and the distribution of this form of infection in the United States. As regards the means by which the germ is introduced into the body there is already some evidence, both from the Philippines and this country, that contaminated water is at fault, but the whole matter needs more thorough investigation. The distribution of this form of infection has hardly been studied outside of the large cities of the East, and although the severe forms of infantile diarrhea are almost unknown on the Pacific Coast, there is little doubt that they exist in the South and Middle West.

**Yellow Fever.**—At the time that the Island of Cuba was occupied by American troops in 1898, yellow fever had been endemic there for 130 years. The disease was not widespread, but was mainly confined to the coast towns, and was particularly prevalent in Havana, the continuous stream of non-immune Spanish immigrants serving to keep up the infection. A great deal of study had been devoted to the disease at this time, and in the years immediately preceding the Spanish war renewed interest had been awakened by th work of Sanarelli, who claimed to have found the casual agent in his *Bacillus icteroides*. His claims had met a good deal of opposition, especially from Sternberg in this country, and many yellow fever experts did not accept his results. In view of the prevalence of the disease, and the constant menace which it offered to our southern states, a commission composed of Walter Reed, James Carroll, Jesse W. Lazear, and Aristides Agramonte was detailed to Cuba still further to study it. The commission presumably started out with a disbelief in Sanarelli's work, for certain of the members had published investigations showing that the *Bacillus icteroides* was closely allied to, if not identical with, the hog cholera bacillus. While Sanarelli's work was repeated as a necessary precaution, and was proved to be erroneous, the commission concentrated its efforts on the investigation of the relation of the mosquito to yellow fever, a relationship which had been insisted on by Carlos Finlay of Havana for nearly twenty years, and which the work of Carter on the time limit between primary and secondary cases rendered probable.

It is not necessary to go into details as to the methods used by the commission in their work, further than to state that they were scientifically above reproach. It will be of interest, however, to consider their results, and the influence which they have had on the practical aspects of yellow fever quarantine. Briefly stated these results were as follows: The proof that Finlay's conception that yellow fever is conveyed by a certain variety of mosquito (*Stegomyia fasciata* of Theobald) is correct. The demonstration that a certain time must elapse after the mosquito is infected before it can transmit the disease; that the causal agent is in the blood during the first few days of the disease; that it can be destroyed by heat, and that it can pass through filters which hold back some of the smaller forms of bacteria. The explosion of the old idea that the disease can be conveyed by fomites, unless these are of a character to allow of transmission in them of infected living mosquitos. These are the main results, and they have led to greater accuracy in our knowledge of the incubation period of yellow fever, increased study of the yellow fever mosquito, and an entirely new conception of the prevention of the disease. Since the original work of Reed, Carroll, Lazear, and Agramonte several independent observers have confirmed their findings, notably Guiteras in Cuba, Marchoux, Salembini, and Simonds in South America, and the working parties of the United States Public Health and Marine Hospital Service in Vera Cruz, Mexico. The investigations carried on under the Public Health and Marine Hospital Service have also supplied many details extending our knowledge of mosquito transmission, of the life history of the yellow fever mos-

quito, and of quarantine methods against the disease. Few discoveries in medicine have led to more rapid and more brilliant practical results than those above cited. The story of the remarkable change in the yellow fever history of Havana achieved by the work of Gorgas reads almost like a romance. When we consider that the annual number of deaths from yellow fever in Havana for the ten years preceding the establishment of the mosquito theory averaged about 500, and that under Dr. Gorgas' administration they were cut down in two years to nothing, we can enthusiastically echo the sentiments expressed in a resolution of the conference of State and Provincial Boards of Health, in which they say: "We regard (it) as one of the most brilliant achievements of the application of sanitary science to public health work ever accomplished." Judging from recent reports it seems likely that Gorgas will repeat his Havana success in the Isthmian Canal zone. We have still to discover the cause of yellow fever, and we have still to ward off its advances in our southern states. So long as our Central and South American neighbors pursue their present lax sanitary methods we are liable to have sporadic outbreaks of the disease in those regions in which the *Stegomyia fasciata* can multiply. As Carter and Howard have shown, this mosquito is widely distributed in the subtropic portions of our country, and it behooves us to continue with the work of mosquito extermination, to increase its range as rapidly as possible, and to keep up with its oldtime strictness the quarantine of vessels, especially sailing vessels, from infected ports. The protection of our land boundaries to the south will, of necessity, be much more difficult, and judging from the recent experience in Texas, it is by this route that infection is now most likely to reach us.

**Malaria.**—The soldiers returned from Cuba and Porto Rico, and later those from the Philippines, offered an opportunity for the study on a wholesale scale of certain aspects of malaria, an opportunity which was grasped by both military and civilian physicians. During and immediately following the Spanish war the accomplishment of greatest importance resulting from this study was the overthrow of the refuge of the careless diagnostician, typhomalarial fever. Those physicians who had studied malaria and typhoid fever carefully before the war, and who had controlled their diagnoses by blood examinations, had always been skeptical about the existence of combinations of the two diseases, and had published from time to time protests against the indiscriminate use of the term typhomalarial fever. It needed the studies of the camp fevers, however, to prove to the satisfaction of most physicians that the combination was exceedingly uncommon, and that when it occurred the malarial fever preceded, or more commonly, followed the typhoid fever. In his remarks on the subject, based on the examination of the blood of 159 typhoid cases at Camp Wikoff, Ewing says: "In no case of undoubted and established typhoid fever were malarial parasites found in the blood in connection with any of these sudden rises of temperature (in typhoid), but only at the onset of the disease or during convalescence," and later in his article, "In short, in spite of painstaking effort, the attempt to find a case of typhoid fever and active malaria progressing simultaneously was unsuccessful." Aside from this, the clinical study of the disease has received but few important additions since 1898, though mention must be made of the valuable studies of Craig on latent and masked malaria, studies which showed how great the danger to a community might be from soldiers returned from the tropics. In his article published in 1904 Craig states that 25 per cent. of the soldiers returning from the Philippines show latent or masked infections, and in a large percentage of these cases the parasite is the estivoautumnal crescent, a stage of the organism capable of development in the mosquito. The same observer cites one company of 60 men, of whom 41 had parasites in their blood, and yet but 14 complained of illness.

As far as the parasitology of malaria is concerned, the past seven years have been marked by great simplification in staining methods, but discoveries of paramount importance have not been numerous. The studies of Craig on estivoautumnal fever have tended to confirm the views of the Italian school as to the duality of its parasite, and the work of Ewing on the tertian parasite has thrown light on its early sexual history in the circulating blood. Working Party No. 2 of the Yellow Fever Institute has been able to show that at the time of the malarial chill there is present in the blood a toxin, and have been able to produce a chill by the intravenous inoculation of filtered blood extracted during the paroxysm.

The study of the distribution of the malarial mosquito has been carried on in a few places, in Boston by Theobald Smith, in the Valley of the Androscoggin by Jordan, and in Baltimore by Hirshberg and Dohme, but the amount of work which has been accomplished in this direction, and the time and money which have been expended in the attempt to exterminate the malarial mosquito, are almost infinitesimal when we consider the territory affected by the disease, and the losses resulting from it. Woldert estimates the annual financial loss in Texas alone at over $5,000,000, and if all the infected zones in the United States are considered the loss must be appalling. Like yellow fever, malaria is a perfectly preventable disease, but to stamp it out requires either destruction of malarial mosquitos, or protection and sterilization of infected individuals. In this country mosquito extermination has always been the favored plan, but before it can be accomplished a much more complete knowledge of the distribution of the anopheles is necessary, and much more thorough education of the public as to the necessity of the work. The danger that the disease may be introduced into uninfected areas by soldiers returning from the tropics is a real one, though, as Theobald Smith has shown, it is unlikely that the estivoautumnal parasite will be introduced into the northern states. Still, we have plenty of southern territory not yet infected, and the extermination of mosquitos would prevent the possibility of such contamination. The question is one which has not yet been seriously considered in large sections of the country, but is, nevertheless, of the greatest importance.

**Filariasis.**—The work of Ashford in Porto Rico, and of Calvert in the Philippines has shown that filariasis exists in both places. In Porto Rico it is probably widely distributed, as Ashford found it in 30 out of 250 soldiers in the Porto Rican regiment. Cases of Gunn and of Brown have shown that infected individuals from this source have already reached this country. In the Philippines the extent of the disease is doubtful. Calvert found the filaria in only two out of 426 Filipinos, but it is to be noted that both of these individuals came from the same district, and it is likely that the disease is much more prevalent in some places than in others. In this country several domestic and imported cases have been reported since 1898. It seems extremely likely that the disease is much more common in the South than the literature would indicate, and that it is often overlooked. The fact that one man, De Sassure, of Charleston, was able to report 22 cases, most of them originating in the United States, is pretty strong evidence that the

disease is much more prevalent than is generally supposed. It is certain that there are present in this country varieties of mosquito capable of transmitting the filaria. As these generally belong to the *Culex* family, which is widely distributed throughout the United States, it seems possible that there is real danger of new districts becoming infected by returning soldiers or Porto Rican laborers. Before the matter can be definitely settled we need more information as to the exact varieties of mosquito which can transmit filariasis, and their distribution in this country. At present it is quite generally assumed that a number of varieties of *Culex*, and at least one of *Anopheles* can transmit the disease. We believe it was Myers who brought forward evidence to the contrary, and the matter is one which needs further investigation.

**Malta Fever.**—The fact that Malta fever was present in Porto Rico was first demonstrated by Musser and Sailer, and later by Cox and Curry. In 1900 Strong and Musgrave called attention to its occurrence in the Philippines, and still later cases occurring in returned soldiers were described by Curry and Craig. The number of cases which have been described is small, and practically all of them are in soldiers and sailors. In the seven years which have elapsed since the first case was reported in this country, no case originating here has been described, and it seems that there is little likelihood of the disease becoming disseminated in the United States. It is within the bounds of possibility, as Curry pointed out, that it already exists in the southern states. In its acute form it is easily confounded with malaria, and in its chronic stage it is generally diagnosed at first as chronic rheumatism. The serum reaction of the disease is so reliable, and the test is so easy of performance, that all cases of doubtful fevers in the southern states should be subjected to it. It seems highly probable that if this is done systematically the disease will be found to be present.

**Trypanosomiasis.**—The relation of trypanosomes to animal diseases was observed in the middle of the last century, and renewed interest has been awakened in these parasites in recent years by the discovery of new forms of animal trypanosomiasis, and by the observations on human trypanosomiasis initiated by the work of Dutton. The presence of the trypanosome infection known as surra among horses and buffalo in the Philippines was noted soon after the American occupation, and the results of American researches on this disease may be found in the valuable monograph of Musgrave and Clegg. Up to 1903 attempts to isolate trypanosomes in pure culture had been ineffectual, but in that year McNeal and Novy published the results of their work on the rat trypanosome. They were able to obtain the first successful pure culture of a pathogenic animal parasite with the absolute demonstration of its causal relation to the disease. Up to this time many observers believed that the different forms of animal trypanosomiasis were due to the same organism, but during 1903 and 1904, Novy, McNeal, and Ward were able to cultivate the trypanosome of nagana or tsetse disease, and also that of Philippine surra, and could demonstrate that the parasites from these different diseases showed variations in structure and mode of growth, Later Lewis and Williams succeeded in cultivating the frog trypanosome, showing that this also differs from the other forms. Some forms of animal trypanosomiasis have appeared in the United States, dourine having been observed in Nebraska. Whether there is any possibility of the introduction into America of human trypanosomiasis will be difficult to determine until we know more of certain forms parasitic in man, and the method of their spread. The form of the disease which is found in the Philippines, and hence most likely to appear in this country, is the affection known in India as kala-azar or dum-dum fever. The parasite of this disease, usually spoken of as the Leishman-Donovan body, has recently been shown by Rogers and Chatterjee to belong to a sub-family of the trypanosomes. The method of transmission of this form of the disease to man is not definitely known so far as we can determine; it is probably transmitted like nagana by an insect, most likely a mosquito. The possibility of its introduction into this country will probably depend on the presence or absence of some insect host.

**Dengue.**—A disease which does not seem to have received the study which it merits, considering its frequency, is dengue, or break-bone fever. The reports of the Surgeon General of the Army for 1902 and 1903 show that in the Philippines it caused, in the former year, 31.67 cases of sickness per 1,000 of strength, and in the latter year 171.39 cases per 1,000 of strength. Presumably it has not been carefully studied in the Philippines, or in the South where it also occurs, on account of its short duration, and the almost absolute lack of fatalities. In the Isthmian Canal Zone it has been studied in the last two years by Sutton and Carpenter. They have shown that it is probably not of the malarial class of diseases, but that it may, as Graham claimed, be transmitted by the mosquito. Their studies of the blood show that it is one of the diseases accompanied by leucopenia and relative lymphocytosis, and their bacteriological studies suggest that a bacillus similar to the influenza bacillus may be the cause. The disease is one which, judging by its past history, is unlikely to spread beyond the southern parts of this country. It is worthy of more extended study by modern methods than has yet been devoted to it, and American physicians in the Philippines and the Isthmian Canal Zone will probably have excellent opportunities to clear up many moot points in connection with this disease.

**Asiatic Cholera.**—During 1902 Asiatic cholera appeared in Manila, spread to the neighboring island, and caused over 90,000 deaths before it was stamped out. The incidence of the disease among the whites was comparatively small, but among the natives it ran rife, owing to their lack of hygienic precautions and the favorable temperature conditions. In many instances the disease was not carried. as usual, by contaminated water, in fact, in the large cities indirect contact through food was a much more frequent method of spread. On account of the violent local reaction produced by Haffkine's cholera prophylactic the natives objected to its use, and as the scattered distribution of the population made it almost impossible to control them, this method was given up. The objections to Haffkine's prophylactic led R. P. Strong to attempt the production of a protective serum lacking in the the irritating properties of those hitherto used. By a process of bacterial autolysis followed by filtration of the culture he was able to produce a practically non-irritating protective. From the experimental standpoint Strong was able to show that animals and men treated by this method presented but little local reaction, yet developed in their blood substances strongly bactericidal to the cholera spirillum. As the cholera had practically disappeared from the Philippines at the time that Strong's work was completed there has as yet been no opportunity to put his method to a practical test. From what we know of

the disease there is little likelihood that it will ever get a foothold in this country under our present quarantine regulations.

**Plague.**—The appearance of plague in several parts of the civilized world in 1900, and especially its appearance in San Francisco and the Philippines, called the attention of American medical men to this disease. Luckily, but few of them had an opportunity to study it, and most of the American work on this disease has been done in the Philippines, where, according to Munson, 970 cases with 812 deaths occurred between January, 1900, and September, 1903. It cannot be said that anything startlingly new was discovered during this period, but a good deal of valuable confirmatory work was turned out. In this connection must be mentioned the work of Barker, Flexner, and Novy on various aspects of the subject, the work of Calvert and Ewing on the occurrence of plague bacilli in the circulating blood, and the work of Herzog and Hare on latent and ambulatory plague. The outbreaks of the disease in Australia, in Honolulu, in Glasgow, and in San Francisco have served to warn us of the necessity of being constantly on guard against its insidious approach. The recent outbreak in Leith, in which, as in the San Francisco outbreak, the origin of the disease was in doubt, shows us that at all our seaports constant vigilance must be maintained, and this must be the case so long as endemic foci are present in Asia. In the preventive work in this country, in this as in other infectious diseases, too much praise cannot be given to the officials of the United States Public Health and Marine Hospital Service, who, besides having to bear the burden of their appointed work, have often also to suffer the slings and arrows of outrageous politicians, and the contumelious taunts of misguided citizens.

**Conclusion.**—We have now considered the more important of the tropical diseases which occur in Porto Rico, the Philippines, and the newly acquired Isthmian Canal Zone, the effects which their study has had on American medicine, and the chances of their becoming domiciled in this country. It has been possible to touch on many important subjects but lightly, and I ask your indulgence for the sketchy manner in which the subject has been treated. Of necessity a number of tropical diseases have not been mentioned, tropical ulcer, frambesia, bilharziasis, and blackwater fever, for example. These diseases are all present in our tropical possessions, but are of relatively minor importance, and as yet have received but little attention from American observers. Two general conclusions are forced on us as a result of this study, one being that many of the so-called "tropical" diseases are widely scattered through the subtropical portions of this country, the other that the acquisition of tropical possessions by the United States has had a markedly stimulating effect on American medicine, and has led to valuable work, some of it of the very first rank, all of it showing evidences of earnest and painstaking effort.

## SEA AIR TREATMENT OF SURGICAL TUBERCULOSIS; WITH REPORT OF CASES.

By CHARLTON WALLACE, M.D.,

NEW YORK.

ATTENDING ORTHOPEDIC SURGEON TO THE SEA BREEZE HOSPITAL, CONEY ISLAND, NEW YORK.

This preliminary report has been prepared for the purpose of acquainting the profession with the progress of the work carried on at Sea Breeze, Coney Island, an experimental hospital for the sea-air treatment of surgical tuberculosis.

The institution has only been in operation one year, consequently complete results cannot be offered, but very much has been done toward proving that it is possible to more rapidly cure advanced cases of surgical tuberculosis by salt air treatment.

Forty-three cases have been under treatment in the hospital, and in selecting them we did not make it a rule to take only incipient or beginning cases, but accepted many advanced cases in such desperate condition that their improvement alone could leave no doubt as to the efficacy of the treatment.

It will be seen from the table that not all our cases have been under treatment an entire year. We were able to admit the patients only as the money for each new bed was forthcoming, so the full capacity of our hospital was reached only on the tenth of May last. Thus we have the opportunity of judging the immediate effects of the cure, as well as the effects of prolonged treatment.

There are four factors in our treatment, namely: (1) Sea air night and day. (2) Cheerful, normal surroundings. (3) Ample, nourishing food. (4) Orthopedic treatment.

The greatest and most successful European hospitals of this class, for we have no American example for comparison, are upon the seashore, for European authorities have experimented and found that there is some curative quality in the sea air which is wonderfully efficacious in the treatment of surgical tuberculosis. Sea water contains 3 per cent. of saline matter, chlorides of sulphur, sodium, sulphate of magnesium, muriate of magnesium and of calcium, and salts of iodine and bromine. (W. M. Powell, M. D., "Sea Air and Sea Bathing in Convalescence." American Textbook of the Diseases of Children, p. 65.) The winds blowing over an ocean, impregnated with all these beneficent chemicals and carrying the spray to the land, together with the large quantity of ozone which we know the sea air to contain, have a stimulating influence upon the general condition, a curative effect upon the local tuberculous lesions, and a sedative effect upon the nervous system. That the sea air does have this wonderful effect upon this class of patiens has been a common observation for years at the Hospital for the Ruptured and Crippled, for in the summer, when some of its tuberculous patients have been sent to inland fresh air homes, others to seaside homes, those returning from the seashore have shown a marked improvement over those coming from the country.

We give our children all of the sea air possible; rain or shine they are out of doors the entire day except for two hours in a tent school on the beach, and at night they sleep in wards where all of the windows are open during even the coldest weather, 12° F. being not an uncommon temperature here in winter. They are, of course, amply protected against the cold by many blankets, and wear warm hoods and jackets over flannel night gowns, also mittens and woolen bed slippers. The same rule about open windows prevails in the dining hall. The patients in the non-ambulatory class spend their days in bed upon the second floor veranda. Under all this radical treatment the children are happy and comfortable. After a few days of gradual acclimatization they become accustomed to the out-door life and do not mind the cold. There has been only one slight case of bronchitis, and coughs and colds are unknown.

The children owe their cheerful, normal surroundings in part to the informal, homelike atmosphere of the hospital, and in part to their free and natural life out-of-doors upon the beach. The nurses are chosen not alone for their professional ability, but for their interest in the children, and they try to give

the individual attention that a child needs. They see to the perfect fulfilment of physical needs, encourage him to do his part toward the harmony of the whole, try to cultivate a cheerful, hopeful outlook by the aid of games and songs and other simple amusement that shall take his thoughts away from himself and his suffering or his deformity. On the beach, they constantly lead the normal child's life. There are all the wonderful things the sea throws up for their amusement and delight. There are the games and sports that children invent, and if one could see the activity of these little patients in their games upon the beach, one would wonder if they were really cripples and if they could possibly be invalids. It would be hard to realize that many of them come from hospitals or tenements where they have hardly been out of doors for months and where their lives have been dullest monotony. They come to us pale and languid, with no desire to be active or to indulge in a child's natural sports; but after a few days they are taking their part in the life on the beach and their cheerfulness and interest react upon the body and hasten the progress of the cure.

The dietary is abundant and of the best. There are five meals a day—breakfast, dinner, supper, and two luncheons. A half hour before arising the windows are closed and the wards warmed for dressing. At half after six the children arise, and breakfast at seven on a cereal, bread and butter, and milk, and a choice from either broiled minced beef, or eggs, or baked potatoes and bacon, or stewed fruit. After breakfast they are out of doors until nine o'clock, when they go to school in a tent on the beach for two hours, with a recess at ten, during which a luncheon of milk and crackers is served. Then they play and have short calisthentic exercises, all out of doors. At twelve they have dinner, consisting of a choice from either roast beef or lamb, or stewed beef or lamb, or chicken and rice, or broiled fresh fish, or minced fresh beef, with two vegetables chosen from the following: Peas, beans, potatoes, rice, spinach, carrots, and macaroni. They always have an unlimited quantity of bread and butter and milk with cream. For dessert there is either some milk pudding, or ice cream, or baked apples and cream. After dinner the children play out of doors until supper time, with a luncheon of milk and crackers and fruit at three. At five they have a very light supper of bread and butter and toast and milk, with either stewed fruit, or eggs, or a cereal. Directly after supper, the babies from three to seven years of age are put to bed, the older children going at seven, the windows being closed in the ward for undressing.

As to the treatment, there is a staff of four graduate nurses and a night nurse. As there is no interne, the head nurse does all the dressings, finishing them by 10.30 in the morning. They are done in rotation, each child coming in his turn from school or play, the non-ambulatory cases being given the preference, and immediately taken after dressing to their beds upon the open veranda.

The medical treatment is in the hands of Dr. Lindsly R. Williams who has, however, never adopted any definite plan of treatment and believes in as little medicine as possible. The advisory board consists of Drs. Walter B. James, Herman M. Biggs, Virgil P. Gibney, John Winters Brannan, E. G. Janeway, Lawrence F. Flick, Newton M. Shaffer, and E. L. Trudeau.

As to orthopedic treatment, the methods are the same as those in general use, but it seemed wise in view of the character of the surroundings and a desire to encourage getting down close to the beach, to introduce one or two modifications of hospital treatment. For example: I have found the American hip brace and the Thomas knee brace unsuccessful because their cross-bars sink deeply into the sand, causing the patient to walk, practically, upon the diseased extremity. I have, therefore, depended more upon plaster of paris for fixation of the parts than upon braces. Whenever plaster of paris has been impracticable, on account of numerous sinuses, an especially strong steel foot-plate, six by four inches, has been attached to the bottom of the stem to take the place of the cross bar. In all cases of disease of the hip and knee, when there has not been more than one sinus, plaster of paris has been used, as it gives better fixation to the part, and a window has been cut over the sinus to permit of the application of the dressing. The ordinary orthopedic treatment is used for disease of the shoulder, ankle, and back.

My experience with these cases at Sea Breeze has tended to prove that tuberculous sinuses heal more readily and permanently when all packing and drainage tubes are omitted and only a sterile absorbent dressing applied. As the general irritability of these cases is such as to cause them almost to collapse at the thought of having their wounds probed and packed, it led me to believe that they would gain strength and local resistance if they were not nervously upset each dressing time. In the beginning, in order to ascertain whether there would be full drainage, the amount of discharge upon each dressing was carefully noted for several days previous to omitting the packing, and compared with that of the succeeding days when packing was omitted. As there was no diminution in the amount of discharge, I concluded that packing or tubing was not essential to drainage. There was also less danger of infection. In no case have we had an infected wound, nor has a sinus healed when it still contained pus. Thirty-four per cent. of the sinuses have healed, and but one has reopened. This treatment is put forward, however, merely as a suggestion, inasmuch as the experiment has not been of sufficient duration to give conclusive results. With the exception of sinuses leading directly to the abdominal cavity, this procedure is being applied at the present time to all sinuses.

We have, during one year's experiment, taken cases regarded as hopeless by the best city surgeons and within a remarkably short time have obtained results beyond all anticipations. Sinuses of long standing have healed, acute pain has rapidly subsided, and, as the summary shows, all but one of the patients have gained in weight in amount varying from thirteen ounces to twenty-four pounds, eleven ounces. In reading the tables one will note the difference in weeks of treatment. One striking gain being that of the child, Annie M——, from the tenements, who has gained three pounds and fourteen ounces during a stay of but three weeks. She had been taken home from the ward of one of the large city hospitals by her father, who said that he wanted to take her home to die, as she seemed to be in a hopeless condition and growing worse. She came to us on May 10, 1905, suffering from tuberculous hip. She was remarkably emaciated, having nine sinuses, all discharging freely, and acute pain. She was immediately put to bed on the second floor veranda, and the ordinary routine and orthopedic treatment was pursued. In less than one week all evidence of acute pain had subsided, and her general condition began to improve, together with a marked improvement of her mental state. It was believed by the attending physician previous to her admission that it was practically hopeless to attempt to improve

Summary of Cases Treated to June 1, 1905.

her condition, yet the table shows what has been done.

We would also note three other patients—Mary McG——, Emil H——, and Elsie K——, who have been admitted since January, all of whom came to us in a very advanced stage, and another patient, John W——, being especially advanced and in a moribund condition. Of these cases, Mary McG——, who is suffering from tuberculosis of the knee, after having been retained in the ward of a city hospital for several months and having steadily grown worse, came to us in such condition that she could hardly walk, with support; yet in a few weeks this same girl was singing and romping with the other children. She has gained six pounds and fifteen ounces, and all pain has left her knee.

The next case is that of Emil H——, who went about the wards of the city hospital in what is known as a "banana cart." Although suffering from a very chronic form of hip disease, complicated with amyloid degeneration of the liver, and having seven sinuses, yet a few days after coming to Sea Breeze he was walking about the verandas, and has gradually gained in strength and local condition, though not so much in weight, owing to his complications.

Elsie K—— came to us in a very weak, emaciated condition and could walk but poorly, yet she goes about now with ease and enjoys her life on the beach, and has gained much in strength, though her weight improvement is only six ounces.

The last is John W——, a most extreme case, in moribund condition, who was admitted April 8, 1905, only upon the urgent request of Dr. Virgil P. Gibney, who said that if we could improve this boy the success of our experiment would be proven beyond a doubt. It seemed hopeless, indeed. The little patient was a mere frame of bones and was suffering acutely. At first, on account of this acute pain, we continued to make use of the weight and pulley which he wore on admission, but within the short space of two weeks this was removed, and he is now absolutely without pain, and wears only a Thomas hip brace. He has gained four pounds and six ounces in seven weeks and five days, and his mental condition is most remarkably improved. I have cited these cases to call your attention to the fact that we have not selected only those of a favorable prognosis.

We feel that we have proven beyond any question that out-of-door treatment in surroundings normally adapted to child life is more effective than the best possible treatment in wards. Fresh air is an essential in surgical tuberculosis as it is in pulmonary tuberculosis.

Whether out-of-door salt air is more efficacious than out-of-door inland air it is the object of this experiment to prove.

There are from 4,000 to 5,000 cases of surgical tuberculosis among New York tenement children alone, and from 50,000 to 75,000 little sufferers from the same disease throughout the country. If we have demonstrated that such cases can be cured if taken into the fresh air and given cheerful surroundings, we have accomplished great good. If comparison of results at Sea Breeze with results in inland hospitals indicates that sea air is preferable to inland air for such patients, we feel confident that the generosity of the American public and the progressfulness of American surgeons will shortly lead to placing the work upon a permanent basis, commensurate with the needs of the American children.

We look forward to the time when there will be a score of places on the American seashore that will make it henceforth unnecessary to look to European sanatoria for proper treatment of surgical tuberculosis.

126 East Thirty-fourth Street.

## THE PREVENTION AND MANAGEMENT OF SUMMER DIARRHEA AMONG THE TENEMENT CHILDREN.*

By CHARLES GILMORE KERLEY, M.D.,
NEW YORK.

Preventive medicine is at the present time engaging the attention of the best minds of the medical profession. The intestinal diseases of infants in summer, classed under the comprehensive term of "summer diarrhea," offer a better field for work in the line of prevention than any other disease of childhood. Considering the high mortality of intestinal disease in the young, there is no disease which deserves more of these efforts. The most potent factors, others than climatic conditions, and environment, in the causation of infant diarrhea are: First, a susceptible, easily infected gut; second, infected food; third, faulty feeding methods.

Sixteen years ago, when a junior member of the house staff of the country branch of the New York Infant Asylum, I gained my first knowledge of the disease in question. While making the rounds one morning early in June, the matter of the summer mortality among the infant population was being discussed with the resident physician, the late Dr. Clarence E. Kimball. I asked, I remember, why they had such a large summer mortality in an institution situated as it was at a considerable elevation, in the open country, constructed on the cottage and dormitory plan, with the additional advantages of good milk, good air, good general surroundings, good nursing, and good medical attendance. His reply was: "Take your pad and write, as we go through the wards, the names of the children that I indicate." I did so, and at the completion of the rounds, he directed that I should keep the list, of thirty names, and remarked that those children would probably be dead before August 1. Seeking an explanation, I remarked that these children were not delicate, nor athreptic. "Yes," he replied, in his characteristic, terse manner, "they may look well; but they have got fool mothers and susceptible intestines. They have had frequent attacks of indigestion and diarrhea during the winter and spring. The mothers cannot be made to feed them according to our directions—they bring all sorts of food from their own tables and give it to their children. On visiting days, when the mothers' friends come and bring cake, candy, and fruit, these children get their share of the cake, candy, and fruit; and I cannot prevent it. These children have but little intestinal resistance, and will furnish us our first fatal diarrhea cases when the hot weather is upon us." I kept my list, and found that the accuracy of his prediction was startling—but four of the children named survived the summer.

During the past twelve years, at the out-patient services of the Babies Hospital and the New York Polyclinic, I have had opportunity to come in close contact with a great many tenement mothers and tenement children. At these institutions we have a clientele fairly regular in their attendance, year after year, as one baby after another appears in the family. At these dispensaries we have a surprisingly low summer diarrhea mortality—about 4 per cent. Why? Because we teach these mothers how to feed and how to take care of their children all the year round.

*Read by invitation before the Society of Health Department Inspectors.

They are taught how to keep the child well. They are given pamphlets of instruction and oral teaching bearing on these points. They are instructed in the care of the bottle and the milk. In case a special article of diet is to be given they are taught how to prepare it. Written directions are given covering the point; nothing is left to the memory. Each mother is told, further, that she must wash her hands with soap and hot water before touching the baby's food or feeding apparatus for any purpose, and that there must be a covered vessel in which the soiled napkins are to be kept until washed. At the first signs of intestinal derangement she is taught to stop milk at once, give a cereal water and a dose of castor oil. It is impressed upon her that a green, watery stool means that the baby is sick and needs treatment, regardless of the season of the year. When the mother learns the above lesson for December, January, and March, she will not forget it in July. Further, as a result of the immediate correction of slight digestive disorders during the cold months we have a much less fertile field for pathogenetic bacteria during the hot weather.

You gentlemen of the Health Department have not made any tremendous impression upon the infant mortality of our city. Your number is increased by the summer inspectors, each man for a given district. The district is too large, and you reach it too late in the season. You are there two or three months in a year. The unsuitable food, faulty feeding methods, and indigestion, are there all the year round; and when you arrive with the hot weather the field is already ripe and you can do but little.

My experience has demonstrated that these mothers are anxious to learn to do their best for the baby; but they are absolutely ignorant of child management. The reduction of the large infant mortality during the summer is to be accomplished by the education of the mothers and by the possibility of their procuring a reasonably pure milk supply. The Health Department should have greater opportunities through a much larger appropriation. The time will come, I hope, when the tenement districts will be dotted with municipal milk depots in operation twelve months of the year under the management of the Health Department, where safe milk may be obtained at small cost. Given such safe nutrition, with the necessary instructions of an adequate number of Health Department physicians and visiting nurses, we soon would find the summer mortality appreciably reduced.

Comparatively few of the cases have pronounced toxic symptoms at the outset. At first there are the evidences of a mild infection; there may be vomiting, with several green, watery stools and an elevation of the temperature of a degree or so. Or the symptoms may be milder still—one or two loose, green defecations. Prompt treatment at this time, even in a crowded tenement, usually means prompt recovery. When the treatment is delayed, or is improper, when the administration of milk is continued, severe toxic manifestations and intestinal lesions are the result almost invariably.

There is one standing order in every household of children in my care, whether in private work in the hospital or in the dispensary. It is as follows: With the first appearance of intestinal derangement give two teaspoonfuls of castor oil and stop milk. Give barley water or rice-water until further advised by me. Our further treatment is simple. The child should be kept as quiet as possible and in the coolest room in the house, and the quarters as spacious as are to be had. Boiled water is given as a drink, and frequent spongings during the very hot days are advised. The cereal water, plain or dextrinized, is to be continued until the acute symptoms have subsided in large measure, regardless of the age of the patient. Barley-water or rice-water is given in the strength of one-half ounce of the cereal to the pint of water. When milk is resumed it is given skimmed, in small quantities, in cereal water; never more than a half ounce in the feeding. If the stools and the continued low temperature are favorable, the milk strength is gradually increased. For some years it has been my practice, in cases which cannot bear even small quantities of skimmed milk, to use condensed milk as a sick diet. This can often be taken and digested without inconvenience, when fresh cow's milk would cause a return of the trouble. From one-half to one drachm is given in a feeding of cereal water. After a few weeks the condensed milk is discontinued gradually by the substitution of one feeding daily of weak and skimmed cow's milk.

Stomach washing is used if there is repeated vomiting.

Various drugs have been used from time to time. The tannin preparations have been tested, and during my four years resident service at the country branch of the New York Infant Asylum almost every known drug that seemed to warrant a trial was given in a series of cases. In the year that followed I had the privilege of attending the clinics of Ranke and Zeitz in Munich, and of Monti and Wiedehoefer in Vienna, where many cases were treated daily. During the twelve years that have intervened in private practice, at the New York Polyclinic, at the Babies Hospital, and at the city department of the New York Infant Asylum, many hundreds of cases have been conscientiously watched and followed day by day. I have learned that there are just four drugs which may be relied upon to serve us in diarrhea. These are calomel, castor oil, bismuth, and opium. Castor oil is given at the onset by preference, the calomel being used only when oil is not retained. In such instances it is given in from one-tenth to one-twentieth grain doses at half-hour or one-hour intervals until one grain has been given. Bismuth subnitrate in not less than ten-grain doses at two-hour intervals, has given most satisfactory results. In order to be of service it must produce black stools—in other words, if some of it is not converted into sulphide of bismuth in the intestine it is without avail. If it passes through the bowel unchanged, no influence whatever will be exerted upon the intestinal contents. This happens in a small precentage of cases. In such the sulphur is supplied by the use of precipitated sulphur, a one-grain powder being given with each dose of the bismuth. The bismuth is continued in the large doses until the child is ready for milk, and then the dosage is diminished one-half and continued until full milk feeding is followed or until constipation necessitates its discontinuance. Opium in diarrhea must be used with caution. I employ it when there is tenesmus with frequent, large, watery stools. Opium should never be given when there are four or five medium-sized discharges in the twenty-four hours. This number is required to maintain drainage. It should never be given in combination with other drugs, for when the stools are reduced to one in four or five hours it should be lessened or discontinued. If it is used injudiciously, in too large doses or continued too long, the cessation of the stools will often be followed by a rise in temperature, prostration, and other evidences of systemic poison due to the retention of the intestinal contents which should be removed. If opium is to be given, I prefer Dover's powder one-quarter to one-half grain every two or three hours for a child one year of age.

As in the case of all good measures, irrigation of the colon has been overdone. Because a baby has diarrhea it does not follow that the colon must be washed out. The child who is having from ten to twenty loose watery discharges in twenty-four hours is quite effectually washed out, and does not require more. The cases which are benefited by the washing are those who have a moderate number of green, loose, mucous stools, with or without blood. In short, the cases to be washed out are those which have something to be removed. I never wash the colon oftener than once in twelve hours—usually once in twenty-four suffices. Various solutions have been used for the irrigation. One is as good as the other if you have enough water; for it is the *cleansing* of the bowel that benefits the patient. I generally employ the normal salt solution; using it warm unless it is desirable to exert an influence upon the temperature. I have used it as cold as 60° F; in cases of very high temperature—105° or 106° F.; while if the patient is very weak, with subnormal temperature and marked prostration, I have used the solution at a temperature as high as 110° F. The irrigation is carried on as follows: A soft rubber catheter, No. 14, English, is attached to a fountain syringe, the bag of which should be held three or four feet above the patient's body. The child must lie on the back or left side, with legs well drawn up. The tip of the well-oiled catheter is passed into the rectum. When an introduction of two inches has been effected, allow the water to pass in slowly. The water will distend the parts and facilitate the further introduction of the tube. Press the folds of the buttocks together until the colon is filled. This in a child eighteen months of age will require twenty-four to thirty ounces of water. When this, or a lesser amount, at least one pint, has passed in, allow the solution to run in and out at the same time.

The treatment and the management of the summer diarrhea in the tenements is more important than its management in the homes of the well-to-do. It is in the tenements that the great mortality of the disease occurs. But a few of the children can be removed to the country. The hospitals cannot care for them except in ridiculously small numbers. They must live or die in their tenement homes. Accepting this fact and knowing how to care for the children we are in a position to advise intelligently. Those so situated should bring this matter to the attention of the Municipal Government. The Board of Health stands between the Municipal Government and the child of the tenements. The Department must have means and power adequate to meet the requirements of the condition.

132 West Eighty-first Street.

## THE TREATMENT OF ACNE.*

By CHARLES MALLORY WILLIAMS, A.B., Ph.B. M.D.,
NEW YORK.
CLINICAL ASSISTANT, NEW YORK SKIN AND CANCER HOSPITAL.

Before taking up the immediate subject of this paper, the treatment of acne, it may be of advantage to review a few points in the pathology and etiology of the disease; for by so doing we may get a clearer insight into its clinical relationships with other inflammatory conditions, and also into the theoretical conceptions upon which we base our therapeutic measures.

The earliest true acne lesion is the comedo, but the comedo itself is a development of a still earlier form, the enlarged pilosebaceous follicle, pouring its thin, oily secretion over the skin, and forming the essential lesion of the seborrhea oleosa. The condition is familiar to all—the thick, coarse, shiny, greasy skin, noticeable particularly on the middle of the face, over the sternum and between the shoulder blades, losing gradually its characteristic features and becoming more and more nearly normal toward the lateral surfaces of the body. A closer examination will show the enlarged openings of the sebaceous follicles, and from each of these a soft, thin, wormlike body can be expressed. In any case of acne, before the conditions have been changed by treatment, this exaggerated production of sebum may be demonstrated easily by drawing the edge of a microscope slide over the nose, with moderate pressure, or by pressing a small bit of skin between the thumb nails. If some of this sebum be squeezed out thin between two slides, the fat removed by washing with a little ether, and the smear then stained with a basic dye, like polychrome methylene blue, the preparation will show countless millions of a very small bacillus, the microbacillus of seborrhea of Sabouraud. And if only the middle of the fat-cylinder has been used, this bacillus will be unmixed with other bacteria.

In many patients this condition of seborrhea oleosa persists unaltered, but in many others there is a gradual change. The superficial epithelium becomes thicker, encroaching somewhat on the follicular openings; while that lining the follicles shares in the same process, constantly exfoliating and constantly renewing itself from beneath, and this mass of partially cornified cells, pushed toward the surface by the overflowing sebaceous matter, is thrown into folds and wrinkles which finally block up completely the mouth of the follicle. This is the beginning of the comedo. But the formation of sebum and the proliferation of the cells continues, until often the diameter of the mass is many times that of the original sebaceous plug. This comedo, the common blackhead, still contains in its center a pure culture of the microbacillus of seborrhea; but secondary infections with other organisms soon occur, the most common and the most important of which is the morococcus, a micrococcus which grows into gray colonies when cultivated. Coincident with the growth of this coccus the papule changes into a pustule—superficial if the inflammation spreads from the upper part of the comedo, deep if it spreads from the lower. This coccus is found in the majority of fresh acne pustules, but sometimes, especially in deep lesions, and more especially in old deep lesions, the microbacillus is found by itself, without any secondary infection whatever; whether in such cases the suppuration is caused by the microbacillus itself or by cocci which have died and disappeared after doing their work, is still undecided.

These secondary affections, which are an essential part of every case of acne except the simple comedo, show the intimate relationship between acne and dermatitis seborrhica, for the morococcus, the commonest of the bacteria of the secondary infections, is almost universally found in dermatitis seborrhica, and may perhaps be its cause. The importance of this fact will become more apparent when we take up the question of treatment.

In this hasty sketch of the pathology of acne reference has been made repeatedly to the bacteria which are always present. Their presence is undisputed: everyone knows they are there, and investigators are fairly in accord as to the particular varieties most often found. But the interpretation of this fact is a very different matter, and here there is a great split in the ranks of dermatologists. Some claim that the

*A lecture delivered at the New York Skin and Cancer Hospital, February 8, 1905.

bacteria are the one and only cause of the disease, and that any constitutional symptoms noticed are purely accidental, or even, as some claim, the result of autointoxication by the products of the growth of bacteria in the skin. A second group of clinicians see in the bacteria only harmless saprophytes; they say that similar bacteria are present in every skin, and that the true cause of the disease is to be found in some disorder of the system which injures the integument by interfering with its normal innervation or blood supply, or by bringing to it the toxines formed in other organs. There is a third group who find some truth in both views; these believe that for the development of acne there must be some sort of predisposition, it may be from indigestion, from constipation, from nerve exhaustion, or from some other general disorder, but this predisposition by itself is not enough to produce acne; there must be also the bacterial infection.

Let us examine these opinions a little more in detail. The first point in favor of the bacterial origin of acne is the presence of a certain definite bacillus in all the lesions. Not only is the microbacillus found in all the lesions, but in the early stages of the development of the disease it is found in pure culture. Various other bacteria are found in the pustules and other involution forms of acne, but none other is found in all the forms. A second point is the striking similarity between the course of an acne pustule and that of other lesions admittedly bacterial, such as a boil or an affection with anthrox. A third point is the result of the test of treatment, for the effect of local antiseptic measures is a matter of common knowledge; time and again, with no internal treatemnt at all, the inflammatory nodules and pustules fade and shrivel under thorough applications of sulphur or of the bichloride of mercury. But against the exclusively bacterial origin of acne stands the certain fact that this so-called microbacillus of seborrhea is present in every oily skin, and may exist there for years, with no development of acne whatever.

Consider now the theory of the constitutional nature of acne. In favor of this is the development of the disease at puberty, and its gradual amelioration or disappearance as adult life becomes fully established. It is impossible to believe that the bacteria happen to reach the skin only at that particular period of life. Secondly, indigestion and constipation, with the accompanying disturbances of circulation and innervation, and the absorption into the blood streams of various toxic materials are extremely common forerunners of an outbreak on the cheeks and forehead. The connection is unmistakable. We meet repeatedly with patients whose complexion is usually good, but in whom every attack of intestinal constipation and indigestion is followed by the development of one or two inflamed papules, which disappear as the intestinal condition improves. Gilchrist has suggested that the indigestion, sluggish circulation, etc., so often seen in acne patients may be caused by the absorption of toxines from colonies of bacteria in the skin, but in the cases I have in mind, the skin is apparently healthy—certainly it shows no sign of inflammatory action—and it is only after some constitutional disturbance that any cutaneous lesions appear. Thirdly, any disturbance of the uterine function is very often accompanied by acne, and in many healthy women, with normal menstruation, each period is accompanied by an outbreak, especially on the chin. Other abnormal states, as cachexia, nervous exhaustion, and the tuberculous diathesis, are so commonly associated with acne, that one cannot avoid the belief in a causal relationship; it is impossible to believe that chance only is concerned in such coincidences. And the internalists, as well as the externalists can appeal to the test of treatment, for many a patient has improved or recovered under purely internal medication. Yet, the effect of all these facts, as arguments in favor of a purely internal causation of acne, is weakened, or shattered even, by certain analogies with other diseases. Ringworm of the scalp, tinea tonsurans, is as purely a parasitic disease as we know, and no one at present doubts that it is caused by the growth of the tricophyton fungus. Yet as a rule tinea tonsurans cures itself spontaneously at puberty; and this being the case, why may we not believe that a disease which begins only at that time is also essentially parasitic in origin? Again, tuberculosis is essentially a parasitic disease, yet it does not develop in every one exposed to it, and is many times observed to follow some failure in the general health.

The third view of the etiology of acne acknowledges both causes, and combines them, but it places them on entirely different planes, and does not consider them at all as mutually exclusive. The acceptance of the belief that the microbacillus is the active essential pathogenic agent in the production of the lesions, does not in the least involve the denial of the equally great importance of the constitutional state. This view is, I believe, the true one. There can be no acne without the growth of some definite microorganism, probably the microbacillus of Unna, Gilchrist, and Sabouraud, any more than there can be ringworm without the growth of the tricophyton fungus, or consumption without the tubercle bacillus. A constipated, or cachetic, or scrofulous, or neurotic individual may have various eruptions, with or without other bacteria, but unless this particular organism is present, that eruption does not take the form of acne. And, on the other hand, no matter how common this organism may be, no matter how diligently it is spread over the surface of the skin, there will still be no acne unless the constitutional state is such as to permit it to develop and to show its specific effect. This predisposition may depend on some evident fault like autointoxication, or it may be so elusive that the most careful search, with our present knowledge, fails to discover it; but it is there, somewhere. In other words, neither growth of bacillus nor constitutional fault is by itself enough to produce acne, but when they are combined in the same individual, they work together to produce the papules and pustules with which we are familiar.

This brings us to the question of therapeutics, for it is in this double origin that we find the key to the correct management of each case; we should correct every general fault discoverable, and at the same time attack the lesions by local measures. Sometimes the one part of the treatment, sometimes the other, will be the more important, depending partly on the departures from normal in the general health and in the personal resistance, partly, it may be, on variations in the virulence of the infecting organism.

It is beyond the scope of this paper to take up in detail the treatment of all the conditions which predispose to acne. Such an attempt would involve writing a treatise on general medicine. But a few suggestions on the management of some of the commoner associated diseases may not be out of place. And here, as everywhere in medicine, the secret of success lies in thoroughness, in a careful inquiry into the previous personal history, and even into the family tendencies of the patient, into his present mode of life, his hours of sleeping, of working, and of eating; the character and quantity of the food taken, the amount of water drunk, and the indulgence of tea, coffee, chocolate, and alcoholic beverages of any kind, the amount of tobacco used, and

its apparent effect, the exercise taken and the time spent in the open air, the question of fatigue, the character of sleep, and whether it be refreshing or no. Systematic investigation of the entire physical condition of the patient should then be undertaken, in a conscientious endeavor to find the weak spot. This may seem to be a great expenditure of energy for a comparatively trivial affection, but it is the method that leads to the best results.

Of all the predisposing causes of acne, the one most commonly met with is indigestion, and particularly indigestion accompanied with constipation. The treatment of the condition is the same, whether acne is present or not. In no case are careful inquiry and rational management more necessary, for often the fault lies in some error of diet or some faulty habit of eating of which the patient is unconscious. The meals may be taken too rapidly, the interval from a light meal to a hearty one may be too long, or that between two hearty ones too short, or the evening meal may be too hearty and taken too near bedtime to allow full digestion. The diet must be adapted to each patient—some must be very careful, others may be liberal. If the digestive organs are competent, any food may be taken, while if they show any weakness, certain articles are apt to give trouble, among these are oatmeal, cream and sugar taken with cereals, fresh hot bread, fried food of all kinds, especially if poorly fried so as to be soaked through and through with grease, pastry and cake, griddle cakes, candy, nuts, cheese, and chocolate, while an excessive amount of meat is sometimes equally bad. Regular habits of going to stool must be insisted upon. Some medicinal treatment also will usually be necessary, but details on the subject may be obtained from textbooks of general medicine.

In women, disease of the sexual organs is a very common cause of acne, and in many women with no apparent disease, or with dysmenorrhea only, each return of the menses is marked by a fresh outbreak as is noted above. Such cases are extremely rebellious to treatment, unless the sexual disorder be first corrected. In many cases, some preparation of ergot, or of hydrastis, or of viburnum, or regulation of the stomach and bowels will relieve the menstrual disorder, and at the same time the acne; in others, more radical measures will be necessary; but in all, until the sexual functions are normal, local treatment of the acne will be followed by temporary improvement only.

Another very common type of patient is the scrofulous. Whatever one's conception of the etiology of the pathology of this condition, it is represented by a distinct group of cases, showing very definite symptoms—a thick, oily, pasty skin, a plentiful growth of hair, a rather thick neck, lymph glands slightly enlarged, or enlarging on slight provocation, frequently with deposits of lymphatic tissue elsewhere, as in the pharynx, usually a mild grade of anemia, and more or less physical and mental lassitude. To get the best results in this class, general measures must go hand in hand with local. They should be kept out of doors as much as possible and preferably at the seashore, and their rooms should be kept thoroughly aired. Exercise, but never to the point of fatigue, must be insisted upon. The diet should be liberal but simple. Of drugs, iron, arsenic, the iodides, and cod-liver oil, will be found the most useful.

The anemic cases also demand their appropriate treatment. In addition to the above classes, where some definite fault is evident, there is a large group in whom it is difficult or impossible to find any one organ or system which we can hold responsible for the general ill-health; the whole organism is less vigorous than it should be, and liable to suffer in any of its parts from the slightest causes. Here the problem becomes more difficult, and for that very reason it is the more important to take the utmost care in directing the daily life, and in using such tonics and alteratives as experience teaches us will be useful—quassia, cinchona, nux vomica, the hypophosphites, mineral acids, sometimes alkalies.

But the local treatment is after all the most important, and here, even as in the internal treatment, the master-word is thoroughness; go into every point in the care of the skin, and go over every part of the affected skin in making applications. The patient should wash the face two or three times each day with cold water, without soap, using no washcloth, but the bare hands, and then dry thoroughly with brisk rubbing. If there are acutely inflamed points, these should be avoided in rubbing, and protected from irritation of all kinds, and especially should never be squeezed or pricked by the patient, as such traumatism only increases the irritation and spreads the infection. The cold water and the friction are both powerful stimulants, and in all ordinary cases their cleansing action is quite sufficient. Hot water, applied at night for a very few minutes only in cases with much inflammation, is often of great service, but its routine daily use by the patient is not advisable, as it is apt to leave the skin coarse and relaxed; and soap also, though very valuable in some cases, is generally to be avoided. The face should be protected also against undue exposure, especially to strong winds, to dust, and to hot, dry air, as over a fire. The effect of this last agent, in conjunction with dust, is seen, apparently, in parts of the Southwest, where acne seems to be unusually common.

The topical applications used must be varied to suit the stage of the disease and the natural quality of the skin. If this is very sensitive, or if there is much inflammation, it is often advisable to begin with a soothing lotion, like milk of magnesia somewhat diluted, or one containing calamin, zinc oxide, and lime-water. After a few days of this treatment, and from the start in ordinary cases, the stronger applications should be used. The basis of most of these, the drug most generally useful in acne, is sulphur. Its action may be varied enormously by using powder, lotion, or salve, by using different strengths of each, by leaving them in place a longer or a shorter time, and by alternating with bland applications. The familiar lotio alba is as useful a preparation as any. For routine use, dissolve one drachm of potassa sulphurata in two ounces of rosewater, one drachm of sulphate of zinc in two ounces of rosewater, and mix the two solutions, when a white or slightly yellowish precipitate of sulphur will be thrown down. It should be used as follows: Shake the bottle thoroughly, pour out a little into a saucer, and with a piece of clean cloth, such as an old handkerchief, sop it all over the diseased area, and let it dry on. Let the patient do this every night on going to her room, and again just before getting into bed, leaving the double coating in place all night. In the morning, let her wash with cold water, dry with brisk rubbing, and immediately apply the lotion as above. The white powder is somewhat unsightly, but it should be allowed to remain as long as possible, the excess being wiped off, if necessary, with a moist cloth. For each application a fresh portion of lotion should be poured out, and a fresh piece of cloth used, for the sake of cleanliness and to prevent any reinfection. I have mentioned these details because in practice just such careful directions are necessary, and the difference between success and failure lies in attention to such minutiæ. The above

formula is a good one for average cases. If the skin be very sensitive the amounts of the ingredients may be diminished; if it be resistant, they should be increased, or fortified by the addition of a drachm or more of precipitated sulphur. If the patient object to the white powder left on the face, a half drachm to one drachm of calamin may be added. If the lotion makes the skin too dry and harsh, a quarter or a half a drachm of glycerin may be added to each four ounces, or the lotio alba may be used at night and a soothing lotion in the morning.

Throughout the treatment, at each visit, all comedoes should be removed by some form of comedo extractor—a small silver tube, with rounded edges at each end, is as good as any—for if allowed to remain, they are not only unsightly in themselves, but form the starting points for papules and pustules.

For many of the severer lesions, large inflammatory masses, the ordinary lotio alba is not sufficiently strong, and for these a lotion containing sulphur pdecip., 1 drachm; ether, 4 drachms, and alcohol up to 4 ounces, may be used in the same manner as the preceding. These applications, with attention to the general health, will reduce the inflammation in nearly every case, but a few will require severer measures. The large, deep, indolent dermal abscesses which sometimes form are little or not at all affected by external applications. They may dry up and resolve if the general treatment be efficient, but even so, their course is sluggish in the extreme, and quicker results are obtained by lancing them and evacuating their contents. A word of caution is here necessary in regard to all such treatment. It must be remembered that acne is not a fatal, not even a disabling disease; patients suffering from it come to be relieved, not of pain and discomfort, but of disfigurement, and any treatment which replaces a temporary disfigurement by a permanent one is worse than useless. The incision, therefore, must be small, and its axis must follow the natural lines of cleavage of the skin, that the resulting scar may be as inconspicuous as possible. After gently expressing the pus, the wound may be left to heal by itself, or a small cotton and collodion dressing may be applied; and this will often end the matter; but occasionally the cavity will refill, and in such cases, in addition to reopening, the interior should be cauterized with a little pure carbolic acid. Such a procedure is very seldom necessary, however, and should be followed only when clearly indicated, simpler means being employed as long as they give any hope of success.

When the active inflammation has subsided, the face will often show the pinkish scars of old lesions, large pores and a few comedoes and indolent papules. At this stage, massage and stimulation are very valuable, removing the dead skin and hastening the formation of new, and by increasing the circulation, favoring the removal of waste products and improving the local nutrition. A good lotion for the purpose contains: borax, 2 drachms; glycerin, 4 drachms, and rosewater up to 4 ounces; while if the skin is very coarse a more stimulating preparation is required, and the official tincture of green soap, first diluted with four or five parts of water, and then used in increasing strength will serve admirably. These lotions should be rubbed into the skin vigorously with a piece of flannel once or twice a day, and the use of the lotio alba continued, for acne is an obstinate disease and any relaxation of treatment is only too often followed by a relapse. If the massage is found too irritating, it should be stopped and soothing lotions applied till the use of stronger methods may be resumed.

One other point should always be considered, and that is the condition of the scalp. We have seen above that the commonest organism of secondary infection is acne, the one responsible, apparently, for most of the inflammation and suppuration, is the morococcus, and this same organism is exceedingly common, if not universal in dermatitis seborrhica. The conclusion is obvious: an acne of the face is almost sure to relapse as long as the focus of infection in the scalp remains. The combination is a very common one, and in all such cases treatment of the scalp should go hand in hand with the other measures, if the best and surest results are to be obtained.

The above scheme considers only a single line of external treatment, and the preparations mentioned are purposely limited, not because the other methods may not be equally useful, but because much better results will be obtained by adopting a single drug as the main reliance, and studying its possibilities in various forms and strengths, than by shifting perpetually from one thing to another in the search for a universal panacea which does not exist. The formulas may be varied enormously; salicylic acid or resorcin may often be added with advantage to any of the above; or the sulphur may be used in an ointment, with or without resorcin, and rubbed carefully into the affected skin. Or, if sulphur is not well borne or does not prove effective, it may be dropped entirely; and after careful cleansing, mercury may be tried and used in any one of almost countles ways, the bichloride in lotions and the red sulphide in ointments being about as useful as any. Such formulas may be found in any textbook of dermatology, and are beyond the scope of this paper, whose chief object is to insist upon thoroughness in the search for and correction of all possible predisposing causes, and upon the necessity for minute detail in all efforts at treatment.

## TREATMENT OF PERTUSSIS IN RELATION TO ETIOLOGICAL FACTORS.

By JOHN BOYD TYRRELL, M.D., Sc.M.,

WATERVILLE, MINN.

In the Nineteenth Century no year has passed without one or more communications on large or small epidemics of whooping-cough. The outbreaks of our day in civilized countries act within always lessening circles, and assume such an indefinite origin that the disease seems to be quite endemic, and would rarely be spoken of as epidemic pertussis, were it not for the fact that here and there in newly settled countries, the *tussis convulsia* transmitted by past ages has been revivified and has become again capable of epidemic ravages.

A disease presenting such distinctive symptoms and so characteristic a course could not be overlooked by so vigilant a mind as Hippocrates and those observing men since his time who correctly diagnosticated the most masked ailments and clearly differentiated so many different diseases. The history of pertussis, therefore, begins with its first unequivocal description, and as long as the earlier physicians had failed to produce in their writings an indubitable impression, we must refer its commencement with certainty to de Baillou, who, in 1578, reported on an epidemic which spread over Paris during that year. Then omitting records of smaller epidemics, we find admirable reports on the large epidemics of 1749 to 1764 in Sweden by von Rosenstein, 1755 in Switzerland by Swinger, 1763 on the Island of Oeland by Wahlbom, 1769 in Germany by Mellin, 1770 in Brunswick by Holdefeund, 1815 in Milan by Ozanan. Yet the origin of the disease must

remain shrouded for all time, since we have received not the slightest conjecture from de Baillou, his contemporaries, or successors, as to how the focus from which the Paris epidemic of 1578 originated. It is certain that at that time it was not observed with epidemiologic interest. At the time of Thomas Willis, pertussis was a well known pest in England; still he did not discuss its origin, and his writings show no concern as to the history and spread of diseases in general.

A collection of records of those times presents undoubted confirmation of those writers who asserted that the home of the virus is in the North Coastland of Europe. Perhaps, too, as Schönlein insinuates, foci arise in the fresh water basins of Switzerland, like intermittent fever or cholera, and spread thence along the course of the rivers by traffic on them. In 1658, 1669, and 1670, whooping-cough raged in London. In 1724 it was observed in Germany and parts of Switzerland. In 1732 and 1733 it spread over the whole of Europe and was carried by English ships to the coast of the American continent. At the middle of the Eighteenth Century, we find pertussis a well recognized disease on the European continent, as well as in America and other extra-European countries. In our times the disease has continued to extend its area of prevalence. Yet it always appears to prefer northern to southern Europe. In North and South America, as in northern Europe, whooping-cough has become an annually recurring disease. According to Danish reports, it is endemic in Greenland (Hirsch). Since 1846 it has been found epidemic in California. The elevated plateaus of Texas seem to be immune. To-day we find an annual endemic recurrence in all known regions, with exacerbations both in morbidity and mortality, every three or four years.

In the hypotheses of all writers concerning the cause of whooping-cough, nothing approaching the positive has been ascertained. However, three dogmatic assertions cover this question; namely, pertussis is an infectious disease; it is a neurosis; it is a laryngotracheal catarrh. Few physicians endeavor to combine the three. Many, in fact the majority of physicians to-day, believe it necessary to defend one or other of these propositions. Yet does it not seem natural to say: whooping-cough is an infectious disease as regards its external cause; it is a neurosis in relation to its most prominent symptoms; and a catarrh in the anatomic localization of its most marked disturbances? To decide this question is not a matter of indifference, since on it depends a rational treatment. Infection would require specific treatment, local treatment would be required for local irritation, and psychic treatment for the psychonervous cough to meet the *"indicatio causalis."* It is generally conceded that pertussis is an exogenous disease, produced by a specific exciting cause, the exact nature of which is not yet known.

When we compare whooping-cough with tetanus, it must be regarded as an infectious disease, attacking particular parts of the nervous system. Compared to an ordinary catarrh due to "cold," there remains to be explained why the typical coughing paroxysm occurs in one and not in the other; but take the disease as one which seems to make the particularly predisposed individual susceptible to the mimicry of coughing, and to its extravagant explosions, and it appears as an epidemic of hysteric convulsive attacks produced in nervous subjects through a psychic contagion, with the catarrhal stage as an accidental forerunner. However, whooping cough is without doubt primarily a catarrh of the upper respiratory tract; during the convulsive stage, it is unquestionably an irritative condition of the nerves presiding over or concerned in the respiratory function. We cannot advance further than this at the present time. Further advances may be made according to the methods of modern neurology, if in all studies of the question the possibility *a priori* be conceded and it be remembered that the original localization of the disease may be different from the seat of the later symptoms, namely, the paroxysms.

Preventive measures against whooping-cough are at present lacking, but to seek a means of protection is not at all unreasonable. Unfortunately, Jahn's words are true to-day: "No dietetic precaution, no purification or strengthening by internal or external remedies, no adjunct, can be mentioned which will prevent whooping-cough, if it is necessary to remain within the limits of the epidemic and of the contagium." The question, then, is: Is there any means by which the disease may be cured, shortened, or its course made milder?

In the treatment of the disease, after so many commendations of different remedies and methods, we can only conclude that every physician is handiest with his own tools. In one work alone, to which I made reference, I found no less than fifty-four different remedies recommended. For those whose work has been met with contradiction, the words of Frederich Hoffman should be borne in mind: "If you wish to understand my arnica, then learn my methods."

Prophylaxis is naturally the first essential, and the first essential of phophylaxis is the avoidance of contact with whooping-cough patients. Schools, playgrounds and kindergartens are most commonly the foci from which the contagion spreads. Therefore, in severe epidemics, these must be closed if prophylaxis is to remain no empty word. Undoubtedly the greatest risk of contagion is during the catarrhal stage, and although at the height of the convulsive stage patients are seldom dangerous, they should be avoided as long as they cough. Very young children should be carefully protected, as should also a child who appears predisposed by heredity, constitution, or previous disease, to a severe course. It is not uncommon, however, for intelligent parents and physicians to leave healthy children exposed in case of a mild epidemic, that they may be immune in case of a more severe outbreak in the future. Yet children under four years, or of consumptive parents, or scrofulous and rachitic children, should be protected in every possible way. Also avoid exposing children who are at the time sick with the measles, especially during that season in which experience has shown serious complications occur most frequently—namely, the end of winter and autumn. Avoid taking cold, since in an epidemic every cold predisposes by making the individual more susceptible to the disease. Removal of sputa and excretory matter away from contact with individuals is a very sensible procedure. In whooping-cough all these rules should be put in force, independent of every theory of the disease.

Mohn, of Norway, insists that he has repeatedly cut short whooping-cough by a thorough disinfection of the room in which the patient lived with sulphurous acid. Bed, clothing, linen, toys, in short, everything with which the patient came in contact, were fumigated for six hours with sulphurous acid, for which twenty-five grams of sulphur were reckoned for every cubic meter. The room was then aired, the patient covered with fresh linen and put to bed. The next day showed the disease to have disappeared. This satisfactory report was confirmed by Schönberg, of Christiana.

Drug treatment, which possesses for the theorist the advantage that its use opposes in no way the

hypothesis of a miasm or contagium, comes to us strongly recommended, and may be tested by any physician. To Binz we owe the general reputation and proper employment of quinine, which to-day stands in the first place among drugs in the treatment of whooping-cough. This drug, properly employed, without doubt diminishes the violence of the attack, and has the reputation of considerably shortening its course. There is one objection to quinine which to some seems insuperable in children's practice, and that is its terrific taste. The physician need not be surprised at his failure in children's practice if from high Olympus he writes his prescription for quinine and hurries away saying: "Now see to it that he gets his medicine. I have something more important to do." Children, however, especially the very young ones, are not so sensitive to the taste of quinine as adults, and the difficulty proceeds not so much from the child as from the physician, who diligently warns about its taste, and the mother, who says, just before giving it: "Poor child—to have to take such medicine." Quinine hydrochlorate is to be preferred to the sulphate, on account of its greater solubility. It can be given in enemata if necessary, but there are many ways of concealing or disguising its taste. Many preparations are on the market to-day which effectively do so. It should be given about three times a day, as many decigrams as the child is years old, or as many centigrams as the child is months old. This is a good general rule to follow. Camphor holds a high place in the opinion of many as a therapeutic agent in pertussis (Jacobi). Given in doses of 0.5 to 2.0 g. daily, it seems to act as a strong restorative in progressive exhaustion and thus affects the course of the disease. The coal tar products are recommended. They are less favorable than quinine properly administered and are frequently dangerous.

In treating pertussis we are obliged to regulate diet. Overfilling of the stomach during the spasmodic stage is an evil, as it provokes cough and vomiting. Consequently, frequent administration of small amounts of concentrated nourishment seems rational, and experiment has proved it so. Pertussis children seem to thrive best on milk gruels of oatmeal, rice, barley and sago. For older children, boiled or roasted beef, boiled or stewed fish, and preparations of malt are excellent. In the case of milk, the addition of a little lime water prevents coating of tongue and buccal cavity, and a little salt retards too rapid coagulation of milk in the stomach. Broths are sometimes excellent for feeble subjects. In irritable stomachs equal parts of whey and egg water. Naturally, constipation produces an increase in paroxysms. Treat this by enemata, suppositories, or small doses of calomel. Symptomatic treatment should be carried out on the principle that each and every symptom should be combated if it threatens, but left to nature if it can be borne without harm or disadvantage. This is worthy of special emphasis. Bronchitis and catarrhal pneumonia are complications in case of full-blooded children which should be guarded against in the catarrhal state. Here emesis is often indicated and justifiable. Tartar emetic in the form of an antimonial wine, a teaspoonful every ten minutes till it acts, is usually sufficient. An enema should be given before emetics are used in children. An expectorant in nauseating doses may be exhibited in the same class of cases.

There is no specific for the prevention of the paroxysm. We can mitigate it, but any and all our means of doing so may fail at any juncture. Special drugs as palliatives have been recommended, as belladonna, morphine, strophine, etc. For violent vomiting, tincture of opium in drop doses is used. Psychic or suggestive therapy in the form of threats and commands has been highly recommended by certain physicians for the paroxysm. Felix Niemeyer tells us that he has heard the wife of a Prussian general, who was a resolute though tender mother, say whooping-cough could be cured only with a rod. This conclusion naturally gave offence here and there, and even aroused public indignation. Yet, supported by the experience of this man and the confirmation of intelligent physicians, this advice must be regarded with considerable emphasis, except in the case of rough and ignorant parents, when it is naturally not suitable. The violent paroxysms of whooping-cough demand palliative treatment. We must realize how much would be accomplished if only this symptom could be combated. Belladonna and, next to it, opium, or its alkaloid morphine, are most highly recommended. The so-called specifics in paroxysms, of which the extract of hyoscyamus received the most attention for a time, are not as efficient as either opium or belladonna. The same may be said to be true of other drugs, as conium, nicotiana, musk, etc. Moreover, many of the modern remedies deserve no more than a passing mention, with the exception perhaps of bromoform, which in a measure replaces chloroform inhalations, which naturally are inexpedient. Bromoform in the form of bromoform water or emulsion is used with quite satisfactory results by many. All preparations containing this drug in solution should be thoroughly shaken up before giving, because of its insolubility and very high specific gravity. Several cases of bromoform poisoning have occurred from ignorance of this fact.

The desire of many physicians to "do something," on becoming discontented with the results of internal medication, or being enticed by the theory of the localization of the disease in the upper air passages, has led to attacks directly on the hypothetic *locus morbi* to prevent the paroxysms. As a result we have reports of cures in eight or ten days by cauterization of the throat with lunar caustic. Inhalations of tannin, opium, carbolic acid, and potassium bromide have been advised. Some have painted the throat with cocaine with good results. The nose has been treated by cauterization and insufflations. The treatment through the ear by means of cotton plugs saturated with camphor should have a passive mention. Any one who has seen the benefit that quickly results from this method of administration of medicine in toothache cannot consider the trial of this simple and harmless method in whooping-cough as frivolous, though absolute results are not to be expected.

Recently Kilmer of New York has reported a series of cases treated by elastic abdominal belts with gratifying results. In controlling the excessive vomiting, as well as decreasing the number and violence of paroxysms, this method is certainly worthy of study and trial. He has shown that the simple wearing of the elastic abdominal belts has cut short certain cases of whooping-cough. The belt simply puts the stomach and abdomen in a splint; it supports the abdominal walls and prevents the relaxation and discomfort so common to all diseases which produce distressing cough. In my own experience I have employed the abdominal belt but twice, and in one of these cases it was used, not because I hoped to benefit the course and severity of the disease, but because the subject was rachitic, with the characteristic pot-belly, and the belt was applied in the hope that by compression and support I could alleviate somewhat the distressing discomfort incident to the cough in such a condition. To my surprise and satisfaction, vomiting ceased almost immediately and the paroxysms were reduced in number and severity to

such an extent that I was forced to conclude that the child was convalescent. I kept this belt on for several weeks after the child had apparently ceased all coughing, and the results, I must admit, were something more than mere coincidence. The second case on which I applied the belt was even more satisfactory, because of the fact, I suppose, that I applied the belt as soon as I was well convinced of my diagnosis. This same means has been used of late to control the vomiting of pregnancy and also of phthisis.

"A method for the treatment of whooping-cough," writes Kilmer, "which will reduce the total number of vomiting spells from 3.951 a week to 463 a week (as was done in his series of cases above referred to), thus showing a reduction of 89 per cent. in vomiting, certainly should be given a fair and impartial trial." Of Kilmer's series there was but one failure to benefit vomiting. Positive good effect on coughing was shown in 66 per cent. of the cases in the series. Positive good effect on vomiting was shown in 94 per cent. of the cases in the series.

## THE MENTAL SYMPTOMS OF NEURASTHENIA.

By EDWARD LIVINGSTON HUNT, M.D.,
NEW YORK.

Neurasthenia is a condition in which the exhaustion of the neurones, coupled with their perverted reaction to stimuli, gives rise to symptoms, both physical and mental, varying in character, degree, and intensity. It is also a condition which is preeminently dependent on the two great factors of life —heredity and environment.

Beard defined it as a neurosis, and as such it has been recognized for a quarter of a century. Of late years, however, the conception of neurasthenia has somewhat changed. There has arisen a tendency to lay more stress on the mental side, and, as a result, an effort has been made to classify it among the psychic disorders. This, while being an advance, and a step in the right direction, seems to me somewhat too radical, and I am disposed to agree with the classification given to it by Kraft-Ebing, who has been most happy in calling it a neuropsychosis.

It is possible to have a case varying anywhere from just beyond the normal to one which is so affected with the doubts, the phobias, and the depressions as to catalogue it among the insanities. The one is almost normal, the other is almost insane. Between these two poles, very nicely balanced, are found the neurasthenias.

The mental symptoms are these: (1) Mental irritability; (2) weakened attention; (3) depression, deep pessimism; (4) introspection; (5) slow cerebration; (6) loss of memory; (7) obsessions, imperative ideas, and impulses; (8) the phobias, morbid, and anxious; (9) temptation to do wrong; (10) impaired judgment; (11) nagging and fault-finding; (12) excited emotional outbreaks.

Mental irritability is an invariable accompaniment of neurasthenia. At times it becomes so great that even those dearest to the patient annoy and irritate. Every subject brought up in the family circle is the cause of heated discussion and argument. So slight a thing as the tone of the voice is taken to denote controversy. Nothing can be spoken of calmly. The asking of a single question opens the flood gates of temper and irrascibility. This irritability is a fairly constant symptom, even in the mild cases. It is one of the most trying and one of the most deserving of sympathy. Perhaps it is the one which the physician most rarely sees. It is especially marked after exhaustion, undue fatigue, or excitement.

Weakened Attention.—Another fairly constant symptom. The patient finds great difficulty in listening to any prolonged discourse, even in following ordinary conversation. The interest may be fervent, but the attention flags. Common accompaniments are gaping and yawning.

Depression, Deep Pessimism.—The consumptive and the victim of cancer are blessed with hope. Their state is one of optimism. Not so the neurasthenic. His state of mind is one of profound depression and deep pessimism. He is hopeless. Even the recital of a parallel case showing complete recovery still leaves him doomed, the one exception. It is a depression of varying degree, at times more profound than at others. The state of the atmosphere and the time of the day are factors in determining its intensity. A dark day, in the forenoon, is apt to cause the deepest depression. On the other hand, the greatest irregularity may prevail, and I have known a patient to be equally depressed on a bright morning. The difference between the depression of the neurasthenic and that of the melancholiac is difficult to define; it is really only one of degree.

Introspection.—If there is one symptom beyond all others which belongs to neurasthenia it is introspection. With the first appearance of neurasthenia comes introspection—indeed, it is often the forerunner. The patient studies himself, with great care he observes each one of the bodily functions, he measures the urine, he saves the fecal matter, he examines the saliva. He watches the physician in his routine examination, and himself quickly learns to note the color of the mucous membranes, the whiteness of the cornea, and the clearness of the tongue. It is quite usual for many patients to take the pulse, while others keep a clinical thermometer and each morning record the temperature. The introspection is, I might say, an almost universal symptom and seems to be among the first, if not the very first, evidence of a disordered nervous system.

Slow Cerebration.—The neurasthenic thinks slowly. He becomes easily confused and agitated and with difficulty can carry out a train of thought. The condition is very constant, and, with varying degrees, is found in almost every case.

Loss of Memory.—The symptom of loss of memory is, I believe, more common among women than men. This may be due to the fact that of the two, the male mind is the better trained. It is fairly constant, although not always present in mild cases. It is of great irregularity, in that on some days it is much worse than on others. It is more a loss of memory for recent events and things, than for those more remote or of childhood. It seems to be largely due to imperfect cerebral coordination, to slow cerebration, and to a lack of receptivity, combined with a weakened attention. As a symptom it strikes great terror to the patient and does incalculable harm in advancing the case.

Obsessions, Imperative Ideas, and Impulses.—These are frequently found among the almost normal, among the neurasthenics, and among the insane. According to Berkeley, they are more common in neurasthenia than in insanity. Heredity and environment can best explain their presence. To the neurasthenic the obsessions present themselves in many and varied forms, and for the time being take complete mastery. They come unexpectedly and, therefore, inopportunely, and demand complete attention, as well as absolute obedience. Unless yielded to, the patient remains in a condition of great unrest and mental distress. They vary in degree and extent from the simple form, in which the patient fears that he may have failed to put out the gas, that he may have forgotten to bolt the door, that he may have mailed the wrong letter, to the more serious

phobias, and the *délire du toucher et du doute,* of which I shall speak next. The neurasthenic is aware of their presence, recognizes them, and, to the best of his powers of resistance, strives against them. Just what causes them is not quite evident. As I have said, heredity and environment are the predisposing, but the exciting cause is not so clear. Kraft-Ebing says they may result from an astounding event, some word, a contrast of ideas.

A patient of mine once wished to return to a suburban town, a distance of twenty miles, where she was staying. She went to the station, bought her ticket, and seated herself in the train. Just before the gong rang she began to question whether it was right to go. She accordingly left the train and came to my office. It so happened that I was out, and she well knew that it was an hour at which I was never at home. Accordingly she returned to the railroad, but this time got only as far as the concourse and did not pass through the gates. She was unable to go any further, and a second time returned to my office. Upon my reassuring her and advising her, she promptly left on the next train.

The Phobias.—It is but a degree from the imperative ideas to the phobias. There are simple fears without either delusion or hallucination. They may be limited to one particular thing or may embrace a group of kindred subjects. The most common and best known are the fear of closed places, the fear of disease, and the fear of contamination. They have been admirably classified by Beard.

The anxious fears are those in which the patient anticipates trouble, in which he expresses a fear of anxiety in the little episodes of every-day life. He is fearful lest he be late for his appointment; he is fearful lest he may have to wait; he is fearful lest the car may be crowded.

Temptation to do Wrong.—A symptom occasionally found.

Impaired Judgment.—An impaired judgment must of necessity follow such a train of symptoms as I have enumerated. The patient does not often display this impairment, however, as his mental attitude is such that he has lost confidence in himself, is unwilling to trust to his judgment, and, therefore, rarely if ever exercises it.

Nagging and Fault-finding.—These two symptoms really belong under the heading of mental irritability. They are well known and well recognized, and exist more especially among men. I have in mind a patient who, whenever he becomes neurasthenic, makes his family miserable by his constant fault-finding. Yet this same man, when in a more stable equilibrium, never criticises.

Excited Emotional Outbreaks.—The mood of the neurasthenic is emotional; he is ever ready to display his feelings, ever ready to have them displayed. As in the case of the imperative idea with no exciting cause beyond a word, a look, or an idea, he suddenly breaks out into an emotional or excited state.

**The Mechanism of the Aortic Valves in Health and Disease.**—R. J. Ewart describes and figures an apparatus he has employed in studying this matter. He finds that under normal conditions the valve during the height of blood flow lies some distance from the aortic wall. As to the comparative elasticity of the aortic valves and corresponding aortic wall, experiments show that during the height of the systole the distance between the highest points of attachment of the valve along the aortic wall is some two or three millimeters greater than by the free edge of the cusp itself. Hence, under the physical conditions that exist during systole, it could not lie against it. When two cups become diseased and the third remains healthy, an unusual strain is put on it, and it stretches somewhat, but this process is attended with serious danger, for at the end of the systole it will fail to open out and an eddy in the blood current will be formed in the sinus which will further tend to keep the cusp against the aortic wall. A disaster of this nature might cause sudden cardiac failure and may explain the sudden death sometimes occurring in slight aortic disease. When all the cusps are diseased, the flow outward ceases at the end of the systole, but the eddies will persist for a short space of time and will naturally tend to assume their rounded shape, and thus meeting the one of the opposite side, will tend to set up an axial stream away from the heart. The regurgitant flow will, to some extent, be retarded by their presence, and it is possible before their complete destruction that a sufficient quantity of blood has entered the auricle from the venæ cavæ necessary for an efficient beat. It is probable, therefore, that these varying motions occurring behind and in the neighborhood of a damaged cusp materially assist in the approach to physical efficiency. Murmurs arise, according to the author, from a simple rhythmical variation in the rate of the flow through the constricted orifice. The rhythm produced is further found to depend upon two factors only—first, the rate of flow, and, secondly, the physical nature of the fluid. The actual shape or nature of the bounding edge has apparently no influence on the vibrations produced. The physical nature of the obstructing material has also no effect as long as the size of the orifice is not materially altered.—*The Lancet.*

**Report of Two Cases of Bony Occlusion of the Right Posterior Naris.**—H. S. Birkett reports two cases of occlusion of the posterior naris due to a congenital, bony partition. The history of the two cases is practically similar. In describing the second, the writer states that the entrance to the right nostril was filled with a considerable amount of mucous secretion, so that it was thought that the patient was suffering from so-called "catarrh." The right nostril was filled with a large quantity of thick, tenacious mucous which was removed only after careful syringing and swabbing. Anterior rhinoscopic examination showed the nasal cavity to be very spacious, due largely to an ill-developed condition of the inferior and middle turbinate bones. The probe showed the posterior naris to be closed completely by a partition which imparted a bony sensation. There was an appreciable diminution of the sense of smell and hearing on the corresponding occluded side. The mucous membrane of the middle and inferior turbinate bodies was paler than normal and sensation was not impaired. Under ether the bony partition was perforated by means of an electric dental drill, the movements of which were guided by the finger introduced into the nasopharynx. The opening thus made was kept patent by a strip of iodoform gauze, which was introduced through it into the nasopharynx. Recovery was uneventful.—*Montreal Medical Journal.*

## THE LUXURY OF TYPHOID FEVER.

Is typhoid fever a necessity, or is it a luxury? Most individuals would unhesitatingly say that they certainly do not regard it is a luxury; unfortunately, there are communities that still think it a luxury, and one for which they are both able and willing to pay, and pay handsomely. Such is the conclusion to which we have come on reading in *McClure's Magazine* for June, an article on "Typhoid: An Unnecessary Evil," by Samuel Hopkins Adams. In that article the writer states that "the average city of 100,000 inhabitants wastes perhaps half a million dollars a year on the luxury of having it, and probably a hundred thousand dollars more in efforts to avoid it. That amount of money properly spent would practically eradicate the disease." He then takes a number of cities and towns that seem to be attached to typhoid, and investigates the conditions, sanitary and otherwise, to be found in these places. Pittsburg receives the place of honor at the head of the list; it has a death-rate from typhoid fever of from 124 to 144 per 100,000. Dresden, in Germany, a city of about the same size, has a death-rate from typhoid of 4 per 100,000. But Dresden purifies the water from the dirty Elbe before allowing her inhabitants to drink it; while Pittsburg prefers undiluted sewage. Even the bottled water for sale there may be loaded with the typhoid bacilli, all in good working order, so there is no excuse for any one in Pittsburg not having typhoid. "It's as much a matter of course as a child's having the measles." But the Pittsburgers will soon be deprived of this luxury, for the city is installing a filtration plant at a cost of seven and a half millions of dollars, and when this is completed they will see their death-rate from typhoid drop as it did in Philadelphia when that city built its filtration plant. The next city to which Mr. Adams refers is Cleveland, which has a "habit of poisoning itself." Typhoid fever in Cleveland is not generally reported by the physicians. "Even in fatal cases there is a great deal of misreporting. Owing to long-continued prevalence, typhoid is an unpopular disease in Cleveland; it is regarded as a slur upon the city. Therefore, upon the reports will be found deaths from 'enteric fever' (the British name for typhoid), 'typhus abdominalis' (the German pseudonym), and 'typhoid pneumonia' or 'pneumotyphoid' (favorite American aliases). A large percentage of fatal 'malaria' cases really belong in the typhoid list." At present Cleveland spends about $300,000 per annum for table waters; it has no present intention of building a filtration plant; but "it has another scheme on hand, an intersepting sewer, which has taken ten years to build already, will take two or three years more, and will have cost $13,000,000 if something doesn't occur to make it cost $15,000,000. Its object is to provide the towns further down the coast with the sewage which now drifts back upon Cleveland, and which will continue to drift back with occasional favoring conditions of wind and water." This, certainly, is very considerate of Cleveland; the city not only drinks its own sewage, but actually passes it on to those other towns that may not have a sufficient supply of their own. Of Chicago, the author says: "To no city in the country, except Pittsburg, has experience been so dear a teacher; and no city has profited so little by lessons so costly." City politics gave the disease a great boom, and the cry of economy caused the first retrenchments to be made at the cost of public health and safety. We have not the space to do more than refer very briefly to much in Mr. Adams' article, but of his arraignment of Cornell in its epidemic of "Ithaca fever" (a new synonym and euphemism for typhoid), some mention is necessary. The typhoid death-rate at Ithaca "reached the appalling rate of nearly 725 in 100,000." The epidemic was, of course, due to the water supply, and as the water company consisted of the very best people in the town no one was called to account. Among these very best people were the "leading financiers, merchants, church members, etc.; . . . the secretary and treasurer of Cornell University was at that time a director of the water company; several of the university trustees had been directors up to within a short time, and their families were still financially interested in the company." With regard to the management of the epidemic at Cornell, we see a little of inside politics. The author says: "The Cornell Infirmary, to which many of the students were taken, was under lay management. There seems to have been little regard for professional opinion. One member of the Medical Faculty of Cornell resigned from the managing committee "because the opinions of a physician were not worthy of the consideration of the laymen of the committee." Another was rebuked in writing, because he took a member of the New York Cornell Medical Faculty to the hospital, which seems, curiously enough, to be against the rules. At a time when all the obtainable aid was necessary, the Medical Faculty, was, as far as possible, excluded from any direction of the infirmary. The result was: Percentage of deaths to cases among students treated at the Cornell Infirmary, 11.5; percentage of deaths to cases among students treated at the City Hospital, 6.7. Conditions of overcrowding and the class of patients considered were the same. That nearly 75 per cent. more cases were lost in the Cornell institution than in the City Hospital may fairly be regarded as the measure of difference between efficient and inefficient management. Finally the death-rate of the infirmary was 1½ per cent. higher than that of outside non-hospital treatment. That is, putting it barely, it was somewhat better not to go to a hospital at all than to trust to the management of the well-meaning trustees of the university institution."

Now, what is going to be done in the matter? Is typhoid fever to remain, or is it to go? The question will, in the long run, be decided by the public. When the inhabitants of any of the cities with polluted

water supply get tired of drinking sewage, diluted or undiluted, and of paying such a terrible tax in lives, and when they insist on a proper public water supply and filtration plants, then and not till then will the typhoid death-rate be as low as it should. If Dresden, and Philadelphia, and New York, and other places can have a respectable bill of mortality so far as typhoid fever is concerned, so can the cities named in this article. But it is for the public to make the demand; often they will have the assistance of the health department, sometimes they will not. The author regards yellow journalism as the greatest non-professional force we have toward better health conditions in our cities. Who shall start the ball rolling towards showing the public that typhoid fever is not necessary, and that as a luxury it is too dear at any price? Shall it be the yellow journals or the medical profession?

## AN EXPERIMENTAL STUDY OF CARGILE MEMBRANE.

The plastic process by which, under certain conditions, adhesions are formed between opposing serous surfaces in the body, constitutes one of nature's greatest safeguards in limiting or otherwise affecting pathogenic processes. Unfortunately, however, nature does not differentiate, and what may in one instance prove an efficient aid, may, in another, be productive of distinct harm. Peritoneal adhesions are often an important factor in abdominal lesions, and it very often becomes the surgeon's task to prevent their formation after operation where not desired. A number of procedures have been advocated in which the aim has generally been to cover all raw surfaces with peritoneum or an efficient substitute. Of the latter the best known, in this country at least, is Cargile membrane, prepared by a special process from the peritoneum of the ox. Dr. R. T. Morris, in order to determine its value, made a series of experiments in rabbits, and concluded that the material possessed distinct advantages in preventing adhesions. Surgeons have not been induced, however, to make any very extended use of the membrane, and with the idea of finding out whether this hesitancy was justifiable, Craig and Ellis (*Annals of Surgery, June,* 1905) instituted a series of extensive experiments in dogs. The material was used in the peritoneal cavity and likewise for the protection of tendons and nerves. Typical operative conditions were provided, and after a sufficient interval, the seat of operation was exposed, the clinical conditions ascertained and histological examinations made of the involved tissues in order to determine the fate of the membrane. The results obtained by these observers do not seem to warrant the favorable opinions previously expressed. In the first place it seems that the membrane does not remain *in situ,* but is readily shifted by the movements of the intestines, so that it was necessary to anchor it with sutures. The experiments show quite conclusively that the material does not prevent adhesions in the peritoneal cavity, and until absorbed, acts as a foreign body and, therefore, as an irritant. Both the plain and the chromacized varieties seem to be valuable, however, in preventing adhesions to wounded nerves and tendons when such structures have been subjected to trauma, operative or otherwise. In replacing destroyed or removed dura mater, the chromacized membrane may also prove of some value. The author's study indicates that the material is destroyed by a lytic substance contained in the body fluid and then partially absorbed. In the tissues it is split into fibrils, this change being accompanied or followed by the penetration of formative cells from the new tissue enclosing it. When the membrane is placed between two freshly incised surfaces, this stimulus towards "healing in" of the foreign material is added to the reparative efforts common to all wounds, and their resultant action must be withstood if adhesions are to be prevented. It must not be concluded, however, that the failure of this particular variety of membrane eliminates the possibility by some means of combating abnormally extensive adhesive processes. Further search will no doubt reveal some material which is better suited to the purpose and will supply a necessary adjunct to surgical technique.

## THE VIRULENCE OF MICROORGANISMS ESPECIALLY WITH REGARD TO THEIR IMMUNIZING POWERS.

Dr. Richard P. Strong, Director of the Biological Laboratory in Manila, has published under the auspices of the Department of the Interior, Bureau of Government Laboratories, a pamphlet on the above subject. The investigations were carried out with two strains of cholera spirilla of different degrees of virulence, designated for the sake of brevity as "virulent" and "avirulent."

The investigation consisted of absorption experiments with the living organisms and guinea-pig immune serum; absorption experiments with the living organisms and rabbits' immune serum; comparison of the agglutination of the virulent and avirulent strain; absorption experiments with the killed organisms and rabbits' immune serum; absorption experiments with the free receptors of the organisms and rabbits' immune serum, and comparison of the immunity obtained with the living virulent and avirulent strains.

The conclusions reached from these experiments were as follows: The virulent cholera spirillum possesses a greater number of bacteriolytic and agglutinable haptophore groups, or these groups are endowed with a greater binding power for uniceptors and amboceptors than the avirulent. The number or the avidity of the bacteriolytic receptors possessed by a bacterium is directly proportional to its virulence. However, the agglutinable receptors do not follow this law—that is, the agglutinable haptophore groups are not necessarily present in the same proportion as the bactericidal ones. While the energy of growth is probably sometimes an important factor in relation to virulence, other phenomena must also be considered. The virulent organism is possessed of a greater number of toxic haptophore groups than the avirulent. The binding power of the free receptors of the organisms for bacteriolytic amboceptors in vitro, is proportional to the bactericidal immunity produced in animals by each, which latter is in turn proportional to the virulence of the organisms from which the receptors were extracted. The binding power in vitro of the dead microorganisms of different virulence for bacteriolytic amboceptors is not in proportion to their toxicity.

The bactericidal immunity obtained by means of

the inoculation with the dead organisms of different virulence or their extracts (obtained by autolytic digestion) is proportional to the virulence of the living strains of the bacteria employed. With the living organisms, while the bactericidal immunity obtained from the inoculation of animals with the virulent organism is greater than that produced with the avirulent, such immunity is not in direct proportion to the virulence of the bacteria introduced.

Dr. Strong, however, insits that these conclusions apply as yet only to the two strains of cholera spirilla employed by him in his experiments, and he is not ready to assert that the conclusions are of general application.

### Tumor and Trauma.

Many competent observers have claimed that traumatism constitutes an important factor in the etiology of neoplasms. Attention is again drawn to this subject by the importance which it seems to have assumed in the domain of accident insurance, these institutions taking increasing cognizance of the possible connection between an injury and subsequent disease processes. Trauma has been defined in insurance parlance as a sudden accident which manifests its effects on the mind or body of the individual without his will or knowledge. This definition is scarcely broad enough, however, for many cases have been known in which the injury manifests itself not in an acute, but in chronic form, extending over a considerable period of time. Herzfeld (*Zeitschrift für Krebsforschung*, Vol. III, No. 1) has studied this subject very carefully, and concludes that pathological researches up to the present show quite conclusively that two factors are necessary for the production of a neoplasm, namely, separation of a germ cell and local irritation. Herzfeld has collected 54 cases in 42 of which it was asserted that some connection was present between an injury and subsequent tumor formation, and in the remaining 12 this was denied. More careful examination of these cases shows, however, that with the exception of a few, no such connection was really present, as in almost all of them it was ascertained that a primary carcinomatous deposit was present before the injury occurred to which it was ascribed by the patient, and, what is more to the point, no connection could be traced between the locality injured and that where the growth took place. In a case which he himself observed, an undoubted chain of circumstances could readily enough be traced between a traumatism and the subsequent appearance of a cancer of the breast. In view of the uncertainty which still exists in regard to this matter, the necessity is apparent for a more definite working rule which may be applied in practice, and this the author attempts to make by asserting that if a neoplasm is to be considered as due to a trauma, it must be formed within a reasonable period of time and at not too great a distance from the locality where the injury was received, the separation of the germ cells took place, and the irritation of the tissues occurred. The necessity for securing a careful and complete history is an important element in judging the merits of each case.

### Defective Vision as an Economic Factor.

In all highly civilized countries defective eyesight is one of the most conspicuous penalties to which its dwellers must submit. The menace of eye-strain in its relation to general health has been pathetically dwelt upon of late by more than one well known medical writer. Without, however, crediting eye-strain with all the evil effects which the perhaps too earnest scribes have attributed to it, the fact must be freely admitted that defective eyesight is a national drawback of a serious nature. In the *Cleveland Medical Journal* for June, 1905, Dr. L. K. Baker discusses the waste of time incident to defective vision, and states on the basis of his own experience that a large percentage of the eye workers of cities are unable to enjoy as many hours per day of those forms of work and pleasure which come through vision, as are those who possess normal vision. The writer gives figures which tend to show that the eyes of at least one person in four have abnormal vision to such an extent as to unfit them for the forms of near work incident to city occupations. Dr. Baker is of the opinion, therefore, that we must recognize the fact that the school course, skilled labor, and other conditions in cities, make demands for visual endurance which one in four of us is not qualified by nature to meet. Knowing this, we must apply prevention. We must modify the working conditions in favor of the eyes and obtain early detection, treatment, and lenses for abnormal eyes. There is one other phase of the subject which needs to be considered. While it is obvious that defective vision is on the increase, and should be prevented or treated, it must also be borne in mind that the treatment should be effective. In the present day there are many so-called opticians who are not competent, and care should be taken by the eye specialist that his patients should be fitted with glasses by a medical man who thoroughly understands his business. Incalculable harm is frequently inflicted upon the eyes of persons suffering from defects of the same who are fitted for glasses by unskilful opticians instead of trained oculists.

## News of the Week.

**Heat Prostrations.**—During the present heated spell in New York City up to noon of Wednesday there had been 134 deaths from sunstroke, and three times that number of prostrations. These figures will be largely exceeded if the heated term continues, as the heat prostrations increase in arithmetical progression with each day of uninterrupted high temperature. The greatest recorded number of deaths from sunstroke in any one day in New York was on July 2, 1901, when out of a total of 553 deaths 332 were reported from sunstroke.

**Treatment of Rabies by the Health Department.**—The New York Health Department is now giving the Pasteur preventive treatment for rabies at the Research Laboratory at the foot of East Sixteenth Street. In addition, the virus is sent out, mixed with a preservative, to be administered by the attending physicians to persons desiring to take the treatment at home. The course of treatment lasts from two to three weeks. It is strongly recommended that wounds inflicted by rabid or suspected animals be thoroughly cauterized with fuming nitric acid, or, if this is impossible, with the actual cautery. Immediate washing out of the wound is also advisable. When possible, it is recommended that animals suspected of rabies be securely chained and kept under observation for eight days. If rabies exists, symptoms will develop so that a definite diagnosis is possible within this time. If the animal is killed, the carcass may be sent to the laboratory for diagnosis. The routine is to make an examination of smears and stained sections of the brain tissue, and also to make animal inoculations. By the former

method a positive diagnosis may be reached in from thirty-six to forty-eight hours. A failure to find the characteristic lesions does not, however, exclude rabies. In the event of a failure to find the lesions, the animal inoculations are relied on for a diagnosis, which usually requires from eight to eighteen days. In sending animals from a distance it is recommended that, if small, the entire body be sent. If this is impossible, the head alone should be sent. The animal or head should be securely fastened in a box, and packed with a considerable quantity of ice and sawdust; the whole to be shipped to the laboratory in a larger box.

**Dr. Armstrong to be Superintendent of Bellevue Hospital.**—At the recent meeting of the Board of Trustees of Bellevue and Allied Hospitals Dr. Samuel T. Armstrong, medical director of the Washington Life Insurance Company, was appointed superintendent of the city hospitals. Dr. Armstrong was born in St. Louis, and was graduated from the St. Louis Medical College and the St. Louis University. After ten years' service in the Marine Hospital Corps, he came to New York in 1890. The construction of the new Bellevue Hospital, the bids for which have already been received, will be commenced as soon as the trustees receive an opinion from the Corporation Counsel on their right to accept alternative bids; that is, bids wherein materials are substituted other than those provided for in the specifications.

**For a Hospital in Turkey.**—The Trustees of the incorporated American Hospital and Training School for Nurses in Constantinople have elected these officers: *President,* W. Ives Washburn; *Vice-President,* George Washburn, D.D., LL.D.; *Secretary,* James S. H. Umsted; *Treasurer,* E. H. Baker, of Bliss, Fabyan & Co. A constitution and by-laws were approved. The organization is indorsed by the Prudential Committee of the American Board of Commissioners of Foreign Missions, and is urgent in its appeal to the public for funds. It is planned to transfer an institution of a similar character founded at Marsovan in connection with Anatolia College seven years ago by Dr. T. S. Carrington, to near the American College for Girls at Scutari. At the outset, pending the building of a permanent hospital and training school, a large building will be hired. Its equipment will be modern. Eight surgeons and two foreign nurses will form the staff. The promoters of the work call attention to the conditions in the Ottoman Empire, which is practically without trained nurses, and naively state that the native physicians, some of whom are rated highly, do not practise surgery, the profession of which "is rendered unsafe by the consequences which follow a case that ends fatally."

**Tent House for Sick Babies.**—A small structure of canvas and wood has been built on the grounds of the Northwestern University Settlement by the Chicago Relief and Aid Society, for the care of sick babies in the most densely populated and poorest sections of the city. The Visiting Nurses' Association has volunteered to supply a corps of nurses to attend the little sufferers, and several hospital physicians have given their services, so that the best care is guaranteed the babies. The Children's Hospital Society furnishes sterilized milk. In addition to this tent house, the officers of the University Settlement have given the use of the kindergarten bathrooms and another large airy room, that will be used to accommodate the babies for whom there is not enough space in the tent house. If the plan proves successful, a large number of similar institutions will be established throughout the congested districts.

**The Health of Philadelphia.**—The intense and protracted heat of the past week, in conjunction with the high humidity, is responsible for an augmented death rate, young children being the principal sufferers. For the week ended July 15 there were reported to the Philadelphia Bureau of Health a total of 548 deaths, 82 more than for the preceding week, and 65 more than for the corresponding week of 1904. Of the entire number, 178 occurred in children under the age of 1 year and 65 more in children between the age of 1 and 5 years. Not less than 120 deaths were attributed to diarrhea and enteritis occurring in children under the age of 2 years. Nine deaths were attributed directly to the heat, 4 in adults and 5 in minors. In adults, tuberculosis of the lungs led the list as a cause of death, being operative in 43 cases. Next came nephritis, with 34 deaths; then heart disease, with 25 deaths, and apoplexy, 19 deaths. Marasmus was responsible for 18 deaths and congenital debility for 17 deaths.

**Large Bequests to Hospitals.**—Three of the large hospitals of this city, viz., the St. Luke's, Presbyterian and Post Graduate Hospitals, are beneficiaries under the will of Margaretta A. Jones, who died on July 11. The residuary estate, which will probably be nearly $1,000,000, is to be divided equally among these three institutions. The principal of the share going to St. Luke's is to be known as the Margaret Jones fund, in memory of Miss Jones' mother. That going to the Presbyterian will be known as the Margaret A. Jones fund, and the Post Graduate devise will form the David Jones fund, in memory of Miss Jones' brother. The incomes of these funds are to be used in providing free beds.

**City Consumptive Hospital.**—The Board of Estimate has made an appropriation of $250,000 for the establishment of the city tuberculosis sanatorium at Mount Hope, in Orange County, N. Y. The property is about seventy-seven miles from this city, and is twenty-five miles from the Hudson River, west of West Point. It has an altitude of 1,250 feet above sea level. The farmhouses and cottages now on the land are to be used for the reception of patients immediately, without waiting for the erection of the permanent buildings, and are said to be capable of accommodating about 400 patients.

**Typhoid Fever in Every House.**—A severe epidemic of typhoid fever is said to have broken out in Collinsburgh, a small town twenty-five miles southwest of Pittsburg. There are about thirty houses in the village, and in every house there are from one to five cases of the disease. Five children have died in one family, and a number of other families have lost one or more members.

**Medical Men Eager for Adventure.**—When Commander Peary announced last week that the surgeon who was to have been a member of his Arctic expedition on the *Roosevelt* had suddenly changed his mind and decided not to go, it is stated that within twenty-four hours over 300 applicants had asked for the vacant appointment. The successful candidate is Dr. Louie James Wolf, an Oregonian who has been in the Bellevue Hospital Dispensary.

**Passengers from Colon Quarantined.**—Twenty-five passengers who arrived from Colon aboard the steamship *Alliança* were transferred to Hoffman Island from Quarantine because they had temperature somewhat above the normal. Under observation only three or four of the men maintained these high temperatures, and none has shown any symptoms of yellow fever. Most of the twenty-five are laborers from Panama or prospectors from Central America.

**Yellow Fever at Panama.**—Although during the

first four days of July no cases of yellow fever were reported from Panama, and at one time only one case was under treatment, at present seven persons are down with the disease.

**Recreation Expert for Panama.**—The conclusion of the Isthmian Canal Commission that proper recreation is necessary for the men engaged in the various branches of the construction has resulted in the engagement of W. E. C. Nazro as recreation expert. Mr. Nazro, who has made a specialty of such matters, will go to Panama, and after investigating the needs of the employees, will make a recommendation to the commission as to plans of recreation, including an amusement hall, clubhouse, facilities for outdoor sports, etc.

**New Brooklyn Hospital Site Selected.**—A piece of property in Dumont Avenue, between Bradford Street and Miller Avenue, in the East New York district, has been purchased by Charities Commissioner Tulley as a site for the new building which is to replace the Bradford Street Hospital. The building will be 200 by 280 feet, but is to be constructed so as to permit the addition of supplementary pavilions as they are required. The cost of the portion to be erected first will be about $60,000.

**Roosevelt Hospital to be Enlarged.**—An annex, 78 by 24 and 48 feet, is to be erected for Roosevelt Hospital between the administration building and the private patients' building on the Fifty-eighth Street side of the grounds, and connected with both buildings by a glass-covered corridor 48 feet long. The new building is intended for dormitories and a kitchen, and will cost about $15,000.

**Ambulance Upset.**—When the Flatbush Hospital ambulance carrying an injured lineman back to the hospital, in charge of Dr. Charles W. Walser, was upset by one of the wheels catching in a rut, the driver, patient, and surgeon were all hurled heavily to the ground. The driver was stunned so that he could not move, but in spite of a severe scalp wound and other injuries, Dr. Walser succeeded in righting the ambulance, replacing his patient inside, and driving to the hospital.

**A New Strauss Milk Laboratory.**—Plans have been filed for a new three-story milk laboratory for the Nathan Strauss charity, to be erected at 348 and 350 East Thirty-second Street. The building is to cost $30,000, and will be fully equipped in all respects for its purpose of providing sterilized milk for the tenement population.

**Miami Medical College.**—The faculty of the Miami Medical College have purchased a lot near the site of the new Cincinnati Hospital, and will put up a new building in the near future.

**Dr. Casper F. Hegner** has been appointed Demonstrator of Histology in the Miami Medical College, Cincinnati.

**Dr. A. P. Ohlmacher** has been appointed Director of the Biological Laboratories of Frederick Stearns & Co.

**Dr. Wyeth E. Ray** has been appointed Associate Medical Director of the Travelers' Insurance Company, of Hartford, Conn. On July 8 Dr. Ray also received his appointment as Assistant Surgeon (rank of Ensign) in the Naval Battalion, C. N. G.

**The Society for the Study and Cure of Inebriety** has elected Dr. H. D. Didama of Syracuse, N. Y., honorary president, and Dr. H. O. Marcy of Boston honorary vice-president.

**Obituary Notes.**—Dr. A. Palmer Dudley of New York died July 16 in Liverpool, England, while on his way to attend a medical meeting at St. Petersburg. Dr. Dudley was born in Phippsburg, Me., in 1853, and was graduated from the Dartmouth Medical School in 1877. He was a professor of gynecology in the Post Graduate Hospital and the Medical School of the University of Vermont, and was attending surgeon to the Harlem Hospital and the Randall's Island Hospital. Although Dr. Dudley was not well when he left this country, no serious fears for his health were entertained at the time of his sailing for Europe.

Dr. Edward Stickney Wood of Boston has died at his summer home at Pocasset, at the age of 59 years. He was operated on last March for carcinoma of the intestine. Dr. Wood was graduated from the Harvard Medical School in 1871, and had been professor of chemistry in the same school since 1876. In 1880 he was a member of the Committee on Revision and Publication of the United States Pharmacopeia. Since 1873 he has been chemist to the Massachusetts General Hospital. He was the author of a number of works relating to analysis, the nature of various poisons, and kindred subjects, and was regarded as an authority of the highest order in his own specialties.

Dr. T. G. Johnston of Ottawa died on July 4, at the age of 56 years. He was a victim of professional duty, having cut himself some time previously during an operation. The wound became infected and pyemia resulted. Dr. Johnston was the Liberal Member of Parliament for the West Riding of Lambton, and was highly esteemed as a public man.

Dr. W. C. Jacobs of Akron, O., the oldest practising physician of that city, died on July 8, at the age of 65 years. While dressing a patient's wound he pricked himself with a pin, and septicemia resulted. He was graduated from the Ohio Medical College in 1862, and served as surgeon through the Civil War.

Dr. William Armisted Moale of Baltimore died on July 12 at the Johns Hopkins Hospital after an operation for appendicitis. Dr. Moale was graduated from the University of Maryland Medical School in 1879, and traced his descent back to Ellen North, the first white child born in Maryland.

Dr. E. H. Yancey of Covington, Ga., died on July 1, at the age of 70 years. He served in the Confederate Army until the close of hostilities in 1865, and began the practice of medicine in 1870.

Dr. C. E. Parker of Princeton, Mass., died on July 10, after an illness of a year, from carcinoma, at the age of 41 years. He was graduated from the University of Vermont in 1889.

Dr. S. L. Sewell of Englewood, Mo., died of heart disease on July 5, at the age of 78 years. He had practised medicine in Jackson County since 1868.

Dr. J. M. Yowes of Centretown, Mo., died suddenly at South McAlister, I. T., at the age 70.

---

**A Simple Substitute for Iodoform and Similar Preparations.**—Sommer says that the following surgical dressing, which has been used with great success in the Japanese hospitals is the invention of Surgeon-General Kikuzi. Straw of any sort, fresh or old, clean or dirty, may be used, but ordinarily rice straw is taken, because it is easily accessible. It is placed in an iron vessel or simply on the stone floor of a room and is lighted, all openings being closed to prevent the access of oxygen. The resulting charcoal is sterile, absorbs fluids with great avidity, costs next to nothing, and can be produced everywhere. Sommer himself frequently uses it in place of more expensive dressings of finely powdered wood charcoal. This stays sterile indefinitely, and has such marked disinfecting and deodorizing properties that it should be more universally employed.—*Reichs-Medizinal Anzeiger.*

(From Our Special Correspondent.)

BIRTHDAY HONORS—SANATORIUM FOR WORKING CLASS—S. WALES UNIVERSITY COLLEGE—A NEW LEAGUE—PROF. HOWARD KELLY—PRIZE DISTRIBUTIONS AND ADDRESSES—HOSPITAL SUNDAY—OBITUARY.

LONDON, June 30, 1905.

A LONG list of honors and promotions in connection with the official celebration of the King's Birthday was issued last night. Among the knighthoods conferred are: Prof. McCall Anderson of Glasgow; Dr. W. J. Smyly, P.R.C.P. (Dublin); Philip S. Jones, M.D., of Sydney; Edmond Sinclair Stevenson, M.D., member of Medical Council of Cape Colony. Surgeon-Major Hale, V.C., receives a K.C.B., Surgeon-General Gubbins, K.C.B., and Col. W. Coates, R.A.M.C. (volunteers), a C.B.

Princess Christian presided yesterday afternoon at a meeting in furtherance of the objects of the National Committee for the establishment of sanatoria for work-people suffering from tuberculosis. It is intended that the sanatoria in question, when erected, shall be maintained by the various friendly societies and other organizations of the working classes whose members are to be benefited by them. The cost of the first sanatorium is estimated at £50,000, for which an appeal is now made. A site has been secured 250 acres in extent. Accommodations will be provided for 200 patients. Some of the friendly societies and other bodies evince great interest, and promise to bear the cost of maintenance. The post-office employees hope to provide for fifty beds. The Princess Christian is president of the committee, and was accompanied by Princess Victoria of Schleswig-Holstein, so with royal support and a popular cause it is probable the first sanatorium for workers will soon be built. Thus another step in pushing forward the open-air treatment is taken, though it is not long since there was considerable discussion as to whether this plan was really all that has been claimed. One would suppose that the needful buildings for trial might be less costly and so more numerous.

The foundation stone of the new buildings of the University College of South Wales and Monmouthshire was laid on Wednesday by H.R.H. the Prince of Wales in his capacity of Chancellor of the University of Wales. His reception was all you could anticipate. At the singing of "God Bless the Prince of Wales" one verse was given in Welsh. In response to the address the Prince congratulated the people of the district, whose liberality has enabled a great part of the scheme to be carried out.

A congregation having been proclaimed, the Prince thanked the deputy, chancellor, court and senate, and guild of graduates for his welcome and for affording him the pleasant duty of honoring the eminent men who were presented for honorary degrees. The recipients were Mr. J. G. Evans, Professor H. T. Jones, Dr. John Williams, Lord Tredegar and Mr. Chamberlain.

Another organization has been set up this week to improve the means of developing the physique of this poor degenerate nation. Among the causes of our decadence the founders enumerate the keen struggle to make a livelihood, the difficulty of obtaining proper dwelling accommodation, the want of fresh air and playgrounds, unwholesome feeding, overcrowding, late hours, premature smoking, drink, and the strain of town life. The "National League for Physical Education and Improvement," as the new association is called, will try to have in every district some agency at work to promote the physical education and development of the young of both sexes. The Lord Mayor presided on Wednesday at the inaugural meeting in the Egyptian Hall of the Mansion House, which was crowded to its utmost capacity. The Bishop of Ripon stated that the causes which tend to impair the health of the nation, as disclosed by the Departmental Committee, ought to be combated by united action, and that the agencies at present engaged in isolated work should have an opportunity of combining, and thus cover the whole country. He moved a resolution to this effect, and remarked that it was not a question as to whether there had been deterioration during a given period, but attention was called to the fact that conditions existed which tended to injure the physical strength of the people. The Lord Chief Justice seconded the motion, and said that after forty years at the bar and several on the bench his experience was that the great cause of crime—second only to drink—was the lack of healthy recreation and innocent amusements among the working classes. Sir W. Broadbent moved that the meeting approve the proposed federation, and after other speeches, including one from Mrs. Bramwell Booth, who declared that the one thing needed was good mothers, the motion was adopted and the new "National League" started on its course.

You know that Prof. Howard Kelly has come over to take rest here, and your readers and others know more of his work than we can tell you; but they may, perhaps, be interested to hear that he had a splendid reception at the Gynecological Society, where he delivered a most important address on Renal Tuberculosis. The meeting was representative, and the expressions of pleasure from various schools at the presence of Dr. Kelly in the flesh must have afforded him all the satisfaction he acknowledged he felt. Dr. MacNaughton-Jones, in proposing a vote of thanks for his brief address, mentioned some of his achievements in gynecology, and went on to say that in no department was his name better known than in that of diseases of the urinary organs, for he stood alone for his skill in dealing with them.

Sir Wm. Sinclair followed, saying he could not do justice to the address in seconding it, but without being eloquent he could be sympathetic. It had been a great gratification to listen. Dr. Kelly had told them that he was practical, and inoculated guinea-pigs for diagnostic purposes. But in this country the prejudice was so great that one might inoculate human beings rather than guinea-pigs. Dr. Kelly was an original man. In this country there is perhaps a slight tendency to run each other down, but when an American discovers anything his countrymen are patriotic about it.

Dr. Mendes de Leon of Amsterdam spoke, and assured Dr. Kelly that not only in England but also in Holland he and his work have numerous friends and admirers.

Dr. Haultain of Edinburgh testified to the peculiar pleasure he had in supporting the vote, for in that distant part of the world called Scotland Dr. Kelly had frequently been and treated them to such an address as that they had just heard. He thought it no trouble to travel so far and bring with his own thanks those of the Scottish members who were unable to come.

Dr. Kelly, in acknowledging the thanks, urged in a charming manner that we must found all our work on moral qualities—that where medical men cordially support one another and where warm affection prevails in the profession there medical work flourishes and medical science stands at the highest. Where jealousy and competition rule, the best work must be stunted.

The Archbishop of Canterbury distributed the prizes at St. Thomas's Hospital on Wednesday, and spoke to the students of the responsibilities for which they were training themselves, and the possibilities which the great advances in medical and surgical science and practice offered them to benefit the lives of rich and poor alike. Never had there been a time when so much was expected from their profession, and it was matter for congratulation that every bit of knowledge acquired was made freely available for everybody.

Sir John Gorst, M.P., yesterday distributed the prizes at St. Mary's Hospital, and discoursed pleasantly about public health. He told the students that the medical profession would occupy a more important position, as all civilized nations were awaking to the importance of the health of the people. Outside the profession those views about health so long held by expert authorities were beginning to spread, and public opinion, the ultimate force by which reforms could be carried out, was backing up the authority of sanitary experts. The Public Health Act Sir John described as a perfect mass of powers which had only to be put into execution by local authorities to produce a much better state of things than existed at present. Much had been done to reduce the death rate, but much more remained, and one great obstacle to progress was the apathy of the poor as to their health.

At the London School of Medicine for Women yesterday Mr. Butlin distributed the prizes and commented on the steady increase in the number of women who took degrees in medicine, though this faculty, instead of taking the first place after arts, is still below that of science. There are about 150 women who have taken the M.B. (London), but more than 250 hold the B.Sc. For D.Sc., out of 16 who tried 14 succeeded. Not more than half a dozen have graduated in law. Mr. Butlin expressed surprise not to find a single female doctor of music, and out of 12 candidates for the degree of Bachelor of Music only 3 had obtained it.

Hospital Sunday has again passed, and the special collections and other efforts were made as usual. The day coincided with the annual visit of the judges to St. Paul's Cathedral, and there the collection was reinforced by a gift of £12,500, being half of a legacy left by the late W. F. Cook for his executors to allot to some central London hospital fund. The testator was head of Cook, Son & Co., of St. Paul's Churchyard, and has bequeathed legacies to various charitable institutions.

Inspector-General A. Turnbull died on the 22d inst.,

aged 67. He was educated at Edinburgh, and qualified L.R.C.S. in 1859, entering the naval service in August, that year. He was surgeon to the *Bacchante* from 1880 to 1882, and in medical charge of the present Prince of Wales when serving on that vessel. He reached the rank of inspector-general in 1896, and had charge of Haslar hospital in 1897 8, in which position he proposed various reforms, including the provision of aseptic operating rooms, which were carried out by the Admiralty.

Surgeon General James MacNab Cuningham (retired), C.S.I., M.D., LL.D., Hon. Surgeon to the King, died on Monday.

Sunderland has lost another esteemed practitioner—Mr. William Alder, who died on the 19th inst., aged 38, from Bright's disease. He had served on the Town Council, and might have become Mayor if health had been spared him, as he was exceedingly popular as a citizen as well as a doctor.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

DISEASE AMONG CONVICTS—VINEGAR IN THE PROPHYLAXIS OF AMEBIC DYSENTERY—PLAGUE IN CHINA—FATAL MALARIAL FEVERS—PERSONAL ITEMS.

MANILA, P. I., May 29, 1905.

THE Insular government recently has had a very unfortunate experience in that many of the prisoners who have been sent to the provinces to work at road construction have contracted various diseases which have disabled them and even resulted in death in some instances. Bilibid, which is the name by which the large Insular prison is known, has had a constantly increasing population during the past two years. The policy has been to find employment for its inmates not only with the view of teaching them useful trades and reducing the cost of maintenance, but also for the purpose of making confinement therein less attractive. With the foregoing purposes in view, large numbers of them have been loaned to the Military to be used in building roads. Several hundred were recently sent to Aebay province to a point near Tobaco. They were apparently in good health at the time of their departure, but soon after commencing to work they developed tuberculosis, dysentery, beriberi, etc. Seventy were recently returned to Manila for treatment on account of suffering with the above diseases, and it is understood that there are at least fifty more who are to be transferred. During the voyage of the first batch sent, smallpox developed among them. The quarantine authorities remanded the vessel carrying them to the Mariveles Quarantine Station. Two additional cases have made their appearance since then. While undergoing quarantine detention twelve died of dysentery and tuberculosis. It is understood that there is to be a searching investigation as to how the prisoners contracted the above named diseases at their camp in the province.

Considerable discussion has been caused by articles in the Manila daily newspapers, which stated that Dr. Stafford of the Civil Hospital had found after much experimentation that raw vegetables might be eaten with perfect safety, so far as amebic dysentery was concerned, provided they were first immersed for about a minute in ordinary table vinegar. In view of the fact that Dr. W. E. Musgrave, of the Government Laboratories, has found amœbæ in the third washing of distilled water used for cleansing lettuce, the claims of Dr. Stafford, if true, would be a great boon to the inhabitants of the tropics. It was reported that the Bureau of Government Laboratories had confirmed the claim, but that has not been done as yet. It was also reported that Dr. Stafford was experimenting upon himself, but in view of the fact that he now has dysentery, it is to be presumed that the vinegar prophylaxis has not proven entirely satisfactory.

The annual outbreak of plague has taken place this year in Hong Kong and Amoy with the same clock-like regularity which has characterized the disease in former years. The increase in the number of cases during the past two weeks has been very rapid. For the past two weeks the number of cases at Hong Kong has been reported at 23 and at Amoy at about 50. If the disease follows the same course as in former years, a still greater increase may be expected each week until well into June, after which time there has always been a gradual decline in the number of cases until November or December, when it completely disappeared. In Manila this year the increase has not yet begun. This may possibly be due to the fact that the rainy season has not commenced yet. The dark days no doubt are more favorable to the growth of the plague organism than the bright sunny days which occur at present.

Last week a case of plague occurred in Cavite, which is situated on the bay about seven miles from Manila and is also the place at which the Navy has its Philippine headquarters. Cavite is in direct communication with Manila by ferries which run almost hourly during the day. The case occurred in a child about seven years of age. According to the history the victim had not been in Manila for over a month. Every effort was made to trace the source of the infection, but no clue was obtained. A house-to-house inspection has been made at Cavite, but no suspicious cases were found.

A very fatal form of malarial fever was recently encountered upon the island of Guimaras. It appears that quite a number of the soldiers who participated at the target practice, which took place some distance from Camp Jossman, contracted malarial fever. Three of them died in spite of the prompt exhibition of quinine, which was given subcutaneously. It is said that the Spaniards had similar experiences which caused them to avoid entirely the section in which the above-mentioned cases were contracted.

Major C. Richard, Surgeon U. S. Army, who has been acting as assistant to Col. Girard, the Chief Surgeon of the Philippines Division, has been relieved from further duty in the Philippine Islands and has returned to the United States.

Major R. J. Gibson, Surgeon U. S. Army, who has been the attending medical officer at the Pasay Garrison, has been relieved from further duty in the Philippines and has returned to the United States.

It has been reported that Colonel J. B. Girard, the Chief Surgeon of the Philippine Division and Assistant Surgeon General, will be relieved within the next few weeks on account of illness. Col. D. M. Appel, Medical Department U. S. Army, will temporarily assume his office until his successor, who will probably be ordered from the United States, arrives.

# Progress of Medical Science.

*Boston Medical and Surgical Journal, July 13, 1905.*

**Neurasthenia; A Study of Etiology; Treatment by Occupation.**—The paper of H. J. Hall may be summarized as follows: Neurasthenia is a very indefinite term, which may be made to apply to a wide range of functional and mental states, which, however, seem to have in common mental instability, irritability, and fatigue. It is a condition always complex, but which may be simplified for therapeutic purposes by the recognition of a neurasthenic unit of which, in combination with an infinite variety of conditions and happenings, social, educational, physical, and psychic, the disease may be said to be built. While much of the diseased state depends upon individuality, and much doubtless on purely physical conditions, very much also depends upon environment. Treatment of symptoms is frequently unsatisfactory, and the broad principle of substitution is advocated, for since the neurasthenic unit is the product of maladjustment with existing conditions, it is probable that entirely new conditions will offer opportunity for better adjustment. The kind of life chosen as most frequently applicable and least likely to foster neurasthenia is that of productive industry. The difficulty of transferring the patient to this, for him, ideal environment is not so great as might at first be supposed. It is desirable to control a practical shop where fabrics and articles of interest and beauty may be made under competent instruction. It must be the real thing, and not a mere play shop. Properly managed, and in suitable cases, the patient forgets his mental difficulties in the light of large new interests.

**Senile Albuminuria.**—A. E. Austin reports the result of a study of the urines of forty-five men, the age limits being sixty-four and ninety-five years, the majority of the patients being over seventy. They are divided by the author into three classes. Class 1 (sixteen patients) gave a positive reaction for mucin, which in over half the cases was referred to prostatitis. Class 2 (nine patients) gave the reaction for serum albumin and globulin. Class 3 (ten patients) gave the reactions for both serum albumin and mucin. Out of forty-five old men, therefore, true albumin was found in the urine of nineteen. Yet none of these men were ill, though many were constipated and most micturated more often than normal. Disturbances in this class of cases may come from imperfect elimination of urea. The author surmised that possibly owing to the continued constipation, the absorption and elimination of indol by the kidneys might account for symptoms referable to the latter, but further research convinced him that the albuminuria was not due to this cause. He is, therefore, inclined to refer the sequence of symptoms to initial prostatic trouble. His general conclusions are that albuminuria is fairly frequent.

*New York Medical Journal, July* 15, 1905.

**Popliteal Aneurysm; Its Surgical Treatment.**—H. M. Taylor calls attention to two facts: First, that in traumatic and sacculated aneurysms, we can and should preserve the lumen of the parent artery, and, second, that in fusiform aneurysms one should arrest the circulation through the sac and obliterate its cavity without disturbing the outside adhesions of the sac. We lessen in this way the danger of too sudden demands on the collateral circulation. He records the personal case of an adult, syphilitic male, with a large popliteal fusiform aneurysm, extending from well up between the condyles to the junction of the upper and middle thirds of the legs. The operation done was a modification of the antyllus method, consisting in proximal and distal ligation of the parent artery, in evacuating the sac, and in approximating by deep mattress sutures the sac walls. The outer adhesions of the sac walls were disturbed as little as possible, with the object of preserving its blood, nerve, and lymphatic supply to aid in establishing the collateral circulation. Diminished trauma and lessened local swelling and pressure, and an increased vascular, nerve, and lymphatic circulation are the advantages gained over proximal and distal ligation with extirpation of the sac. Capillary drainage was introduced into the sac. The drainage was very free for a week. The patient's recovery in all particulars was satisfactory.

**Papilloma of the Kidney; Nephrectomy.**—The patient of J. B. Boucher was a woman of forty years, with attacks of colicky pain in the region of the left kidney, extending down the course of the ureter to the groin, and at first associated with menstruation. Finally they occurred as often as three times a week, and she rarely went ten days without one. Before and during the attack no urine was passed, but after the attack she passed large quantities (often two quarts) of clear urine. Occasionally it was dark, but contained no stones or blood. Examination of the abdomen was indefinite, and exploratory incision was decided on. The right kidney was in good condition. The left was found in almost normal position, but hard and small. A nephrectomy was done, and the patient made a good recovery. Incision of the organ removed showed the cortical substance to be somewhat contracted and harder than normal. Extending into the ureter from pelvis of kidney two small papillary tumors were found, so attached that when the kidney was in position the tumors passed by each other in such a way that they apparently occluded the entrance of the ureter. It is not clear just how these tumors produced the painful crisis. If it was by occluding the ureters, it seems strange that there was not an enlarged kidney, or at least a condition of hydronephrosis. It is difficult to explain why there was such a large quantity of urine passed after each attack, unless it was of reflex origin.

*Medical News, July* 15, 1905.

**Two Cases of Epilepsy, the Result of Gastrointestinal Disturbance.**—The first case of F. H. Murdoch was a girl of eighteen years, whose stomach disturbances began one year previous to her attacks of petit mal. The latter then began, and increased in frequency, so that she had eight or nine a day. Examination showed that the stomach reached, on inflation, the navel, and that the right kidney was movable in the second degree. Gastric secretions were normal, but in the morning, before eating, the organ contained much mucus mixed with bile. The treatment consisted in lavage, proper diet, and, for an accompanying anemia, arsenic and wine. The petit mal ceased after the first lavage and did not return. After a summer's stay in the mountains, the patient was completely restored to health. The second case was that of a man of thirty, two years with attacks of grand mal, with intestinal disturbance. On inflation, the stomach reached to a point one and one-half inches below the navel, while the ascending colon was considerably dilated. There was a history of but one convulsive attack. Regulation of the diet and daily colon flushing, with normal saline, relieved all the abdominal symptoms, and the convulsive attack did not recur. The author admits that it is impossible to be sure on this latter point, as epileptic attacks often come on at night, and a person may be epileptic for years without knowing it.

**Three Cases of Primary Sarcoma of the Stomach.**—The cases are reported by Harlen Brooks, his patients being respectively females of fifty-seven and fifty years, and a male of fifty-seven years. The growths were in the order named round-celled sarcoma, fibrosarcoma, and angiosarcoma. The autopsy findings in the three instances are recorded in full. The symptoms were in general those of malignant disease of the stomach. Brooks states his belief that primary sarcoma of the stomach is much more frequent than is generally thought to be the case. Unquestionably this is due to the fact that microscopical examination of tissues removed post-mortem is not invariably resorted to. The four recorded by him have been discovered in a series of some 1,200 consecutive autopsies, and in each of these instances the gross specimen aroused his suspicion as to the usual nature of the growth. It stands to reason that gastric sarcoma may, in many instances, resemble the more common gastric carcinoma, and it is his firm belief that, were every case of stomach neoplasm examined microscopically, we would find sarcomata much more frequent than his statistics indicate. There is less tendency to involvement of the gastric mucosa and more toward the infiltration of the muscular walls than with carcinoma. Metastases are apparently less frequent and of later appearance than with carcinoma, and the course of the disease is longer in sarcoma.

*American Medicine, July* 15, 1905.

**"Gall Spider Cases."**—Robert T. Morris says webs of peritoneal adhesion are found in the bile tract region so commonly that they have come to be looked upon almost as a normal characteristic of the region by post-mortem examiners. The significance of these webs of adhesion has been overlooked in the same way as we overlooked the significance of adhesions in the cecal region previous to our knowledge of the subject of appendicitis. Peritoneal adhesions in the bile tract region cause symptoms that are commonly diagnosticated as belonging to a large group of gastrointestinal disorders, and the author believes that the subject is one that is to attract the widespread attention of physicians immediately. Rules are given for making the diagnosis in "gall spider cases," as the author characterizes them. He removes the gall-bladder and prevents recurrence of adhesion by employment of Cargile membrane or of the film method. The subject is a new one, but the cases are so common that practitioners will find them frequently as soon as they have begun to look for them.

**Blood-Pressure Observations for the Practising Physician.**—Clinton E. Brush speaks of the importance of using a cuff at least 12 cm. wide, as the error in cuffs that wide or wider may be disregarded. The importance of obtaining both diastolic and systolic pressures is emphasized—the method of Strassburger for determining diastolic pressures being deemed sufficiently accurate for ordinary work. He concludes: (1) Both systolic and diastolic pressures should be taken. (2) The cuff on the instrument should be at least 12 cm. wide. (3) With the wide cuff, the normal systolic blood-pressure for the healthy adult male is nearer 110 mm. Hg. than it is 130 mm. Hg. (4) The chief value of blood-pressure observations lies in the lead they give in regard to indications for and results of treatment. (5) In a few conditions they are of diagnostic value. (6) In many conditions blood-pressure observations are of no practical value.

**Cholemia in Neurasthenia.**—Hubert Richardson reviews the etiology and symptomatology of cholemia, calling attention to the nervous symptoms with which it is associated. The presence of bile pigment in the plasma and the cerebrospinal fluid in certain cases of neurasthenia is the primary cause of the disease. He recommends mercury in small doses in combination with sodium glycocholate mass, with the administration of large quantities of water containing the inorganic salts of the plasma in normal proportion as well as alkalies in full doses. He considers this form of neurasthenia has a bad prognosis, the disease often progressing to a true insanity.

**Recent Views Regarding the Treatment of Nephritis.**—James S. McLester thinks that the practice of giving large quantities of fluids in cases of acute nephritis is still very general and, owing to the intolerance of the acutely inflamed kidney to water, is productive of much harm. As a diet in this disease he indorses a milk and cream mixture. In chronic interstitial nephritis he advocates moderate restriction of fluids to relieve as much as possible the heart, and thinks the diet usually prescribed is too low in proteids to maintain the necessary nutritive equilibrium.

*The Journal of the American Medical Association, July* 15, 1905.

**Fractures of the Upper Maxilla.**—Raymond Russ describes a form of splint for fractures of the upper jaw, consisting of a headpiece of heavy wire or whalebone and an interdental plate of aluminum molded to the jaws, the two parts being united by strong rubber bands, and permitting the taking of food and power of speech during the mending of the bone. The interdental plate is, for part or all of its extent, bent upward so as to form a sort of gutter filled with softened dental compound, which moulds around the teeth, keeping them in place. Two lateral arms pass out of the mouth over the bicuspids, affording attachment for the rubber band. The splint can be easily removed and cleansed by boiling.

**The Ethics of Pharmacy.**—H. W. Wiley discusses the

subject of the duties of the pharmacist as regards the interests of his own profession, those of the physician, and those of the public. The relation of pharmacy to his own profession, he thinks, can be defined in a few words: That he should keep and dispense standard medicines and those of the purity and strength required; that he should avoid substitution, and that he should avoid illegitimate commercialism. In other words, the essentials are purity of products, legitimate profits, and freedom from debasement and substitution. As regards the medical profession he sums up briefly the ethics of pharmacy, as the training of skilled pharmacists able to compound in the most artistic way, and with the best results to the patient, the prescription which the physician may present. He deprecates the use and sale of proprietary remedies. This he considers as one of the greatest evils of the day. In his relations to the public he believes the pharmacist should be protected from the sale of drugs by unqualified persons, and he urges on the pharmaceutical profession the propriety of educating the public in matters of temperance and deliberation in the use of iced drinks, etc., of which custom has made him the dispenser.

"Full many a man both young and old
Has gone to his sarcophagus
By pouring water icy cold
Adown his hot esophagus."

This would be, he thinks, a good prophylactic motto for the popular soda fountain. The druggist also should not allow himself to keep a saloon, and he should not sell the proprietary remedies in which the principal ingredient is alcohol. If not allowed to sell the ordinary intoxicating drinks, he should not sell these substitutes, at least not without taking out a license. In many cases, the pharmacist is an emergency physician, and should be able, therefore, in his relations to the public to give first aid in the way of drugs and other help. He holds there should be a mutual friendliness between the druggist and the physician, since each must at times exercise the functions of the other, and he would like to see more instruction in pharmacy in medical schools, and vice versa.

**Traumatism of Right Kidney.**—Charles B. Dyde reports the case of a young man who was kicked by a horse, in the right lumbar region, ten days before he was admitted to the hospital. At first the patient refused operation, although he had severe pain, swelling of the right side of the abdomen, and bloody urine. After several weeks he consented to an operation. Kocher's oblique incision was made, but no trace of the kidney could be found. There was severe hemorrhage on the table, but was controlled by packing with gauze. The patient lived eighteen hours, and autopsy revealed the following unusual and remarkable condition: The right kidney, entirely free in the cavity, which contained two quarts of blood clots, was broken into three pieces, retaining not the slightest connection with vein, artery, or ureter. His days had been prolonged by the system of adhesions, which walled off and limited the hemorrhage, and the gradual stretching and tension of these, as the swelling increased, had created a great deal of the abdominal pain.

*The Lancet, July* 8, 1905.

**Automatic Flushing of the Stomach in Certain Cases of Vomiting.**—The histories of four cases are given by W. H. Bennett. The method, which the author learned from a patient who took the treatment of his case into his own hands against the advice of the physician, consists in drinking as much as the patient desires of ordinary cold or tepid water, or other perfectly bland fluid. As thirst is, in the first instance, the main thing to be obviated, plain water is preferable, as more of it is absorbed than of any other liquid. The effect of the administration of water in this way, which is quite the contrary of orthodox teaching, is really to bring about a very frequent automatic washing out of the stomach, and it will be found by the time the patient has taken, say, a pint or one and a half pints of water, which he will greedily do, that the vomit, although occurring quite as frequently as, or perhaps more frequently to begin with than before, becomes clear; it loses its smell, the offensive taste is gone, and the patient's disgust is entirely removed. In such a case it is a revelation to watch the change that comes over a patient's countenance as he is allowed to quench his thirst, and as the vomiting, after taking free libations of water, becomes inoffensive to the taste and smell. The special class of cases of vomiting to which the author refers consists of those abdominal conditions, with and without operation, in which, for some reason or other, the normal functions of the intestines are so disturbed that frequent rejection of stomach contents takes place.

**A Case of Hypertrophy of the Mammary Glands.**—J. Darquier relates the case of a woman of Beunos Ayres, thirty-five years old, in whom the right breast, and later the left, became enormously enlarged. The increase in size was slow and painless, while the general condition was good. When first seen, eighteen months after the beginning of her trouble, the mammæ hung down like huge saddlebags to the level of the umbilicus. Abrasions, due to friction, were present on one side, but the feel was that of normal mammæ. The skin was much thickened, but not adherent to the deeper structures. Some few enlarged glands were found in each axilla. No improvement followed the iodide internally and compression externally, so both breasts were removed (a month intervening between the two operations), and the patient made a good recovery. Examination showed that the breast tissue was formed of fibrous meshes with but few cells, and a considerable number of vessels with thick, fibrous walls. The glandular acini were atrophied by compression, and only a few surrounded by fibrous tissue, were healty. The pathological diagnosis was chronic fibrous mammitis, or diffuse fibroma of the mammæ.

**Perforated Gastric Ulcer with Fatal Hemorrhage from the Bowel in an Infant Forty-five Hours Old.**—The first symptom in the case reported by A. G. Bisset was hemorrhage from the anus. There was no history of hemaphilia, syphilis, or phthisis, and the child was not jaundiced. The bleeding continued, and the child passed into a state of collapse and died, various remedial measures being without avail. A provisional diagnosis was made of some form of ulcer pretty low down in the bowel. This was disproved by the autopsy, which revealed a typical gastric ulcer of the acute form, with clean-cut, punched-out margins on the posterior stomach wall near the lesser curvature, and about half an inch from the cardiac opening. The ulcer was completely perforated, and, as some shreds of mucoid material were found adhering to its peritoneal aspect, the posterior abdominal wall was again examined, and a little of this blood-stained mucoid matter was seen lying in the situation which the ulcer must most probably have occupied, evidently indicating that adhesion of the ulcer had actually taken place at this point, but had become separated during the removal of the stomach from the abdomen, and had been the means of preventing the escape of the blood into the peritoneal cavity. The ulcer was circular in form and was almost the size of a threepenny piece on its inner surface. The paper closes with some statistics as to the frequency of occurrence of gastric ulcer in young children. The author finds that in the recorded cases actual perforation is extremely rare. In this particular case there was no vomiting whatever. Bisset refers to the origin of the lesion in his own case to the vigorous gastric peristalsis set up by the milk imbibed, though assuming that there must have been some previously weakened area on the stomach wall. For the latter, he is unable to account.

**Note on the Examination of Cultures and Smears from the Throat and Nose.**—W. T. Gordon Pugh commends the use of the following stain: "One gramme of toluidin blue is dissolved in 20 c.c. of absolute alcohol and distilled water, one liter to which 50 c.c. of glacial acetic acid are added. The stain is applied to the preparation for two minutes. When examined in a bright, artificial light, all the Babès-Ernst bodies, whether in bacilli or cocci, are stained a reddish-purple, while the bodies of the diphtheria bacilli stain a faint purplish-blue; those of other bacilli acquire a pale but more definite blue tint, as do also most of the cocci.

*British Medical Journal, July* 8, 1905.

**The Nature of Tabes.**—William R. Gowers gives as the two essential symptoms of tabes, loss of the knee-jerks and incoordination of the legs. He declares that it is open to question whether locomotor ataxia is primarily a disease of the spinal cord. The posterior sclerosis of the cord is degeneration of the tracts adjacent to the posterior median columns. It is a secondary, upward degeneration, which occurs above any transverse lesion of the cord. It does not occur, says the writer, below a lesion, therefore the fibers have their vital center below. But the same degeneration occurs if the posterior nerve roots are destroyed. This is most significant. It shows that the fibers of these columns come directly from the posterior roots. They are fibers which have their vital centers in the cells of the posterior ganglia. Another symptom besides those mentioned is hypotonus, or diminution of muscular tone. We can conceive that the ataxia of tabes and the loss of the knee-jerk may be entirely due to the degeneration of the sensory muscle neurons, to the effect of the loss of their impulses on the spinal and cerebral processes. Whatever the morbid influence which causes tabes, it may penetrate more deeply into the nervous system and pass beyond the sensory neurons on which its influence acts first and chiefly. It may even involve the motor centers, as those of the eyeball muscles, and even those of the limbs, in the spinal cord. The visceral symptoms and the various crises also occur, but of these we do not know the precise mechanism.

However, the cause of the disease acts chiefly on the sensory neurons, and thus its essential symptoms are produced. Toxic agents derived from without, such as arsenic and alcohol, may derange nerves of special function and give rise to symptoms precisely like those of tabes. A similar effect is produced by poisons generated within the body. The organisms of specific diseases generate toxins in part directly, and in part indirectly. These organisms produce poisons, and also substances which are not poisons, but which derange the formation of albuminous substances and convert them into nerve poisons. The writer, in speaking of the relation of tabes to syphilis, says that we may regard as justified the assertion that syphilis must be regarded as a *conditio sine qua non* of the occurrence of tabes.

**The Increase in the Consumption of Animal Food: A Survey of the Past Fifty Years.**—Chalmers Watson declares that there is probably a widespread opinion among medical men that any deterioration which may be proved to exist in the present generation has a direct relation to the alterations in the dietetic habits of the country in the present and past generations. A study of the available data conclusively proves that in the last fifty years there has been an enormous increase in the consumption of animal food. The writer then touches upon the geographical distribution of disease. It is said that appendicitis is almost unknown among the natives of India in those districts in which the staple article of food is rice. Chlorosis is also extremely rare. Diabetes is so prevalent that it might be called the gout of India. These facts are suggestive. It is reasonable to think that diet may play an important part in the occurrence of other diseases of a more acute nature. It has been suggested that the relative immunity to typhoid fever in the Japanese army may be partly accounted for by the nature of the Japanese dietary. The writer then appends some interesting charts, in which he shows the remarkable increase in the consumption of meat in the British Isles in the past fifty years.

*Berliner klinische Wochenschrift, June* 26, 1905.

**A New Palliative Operation for Benign Stricture of the Rectum.**—Lenk calls attention to the fact that the results obtained in the treatment of this affection by major operations, such as resection, are not very encouraging. For example, Koenig, out of six cases had one death and five relapses, and in the experience of most surgeons resection without a relapse in the course of years is a rarity. The alternative, that of making a permanent artificial anus, is a terrible infliction for the patient to be obliged to resign himself to for life. In three cases that he has lately had to treat the author has employed the principle of simple incision of the stricture with excellent results, and he recommends it for those cases which, in consequence of the inadequacy of dilatation with bougies, or other treatment, are considered ripe for one of the major operations. In carrying out the procedure he lays great stress on securing asepsis of the operative field by irrigation and the use of antiseptic powders. The day before the operation the rectum above the stricture is plugged with a large tampon of iodoform gauze and opium is administered. The operation is done with local anesthesia, under control of the eye, through a speculum. A quadrilateral section of the cicatricial tissue is then excised, the layer removed not being more than one centimeter in thickness in order to lessen the chances of subsequent contraction. The stricture is at once dilated to its fullest extent in order to determine whether its caliber has been sufficiently increased, and if not, a second area is excised on the opposite side. The author's three cases gave excellent results under this plan, both as regards preservation of the patency of the intestine and improvement of the existing proctitis.

*Münchener medizinische Wochenschrift, June* 27, 1905

**Granulations in the Lymphocytes of the Blood.**—Schridde describes observations he has made on the lymphocytes which he believes will be of great assistance in determining the origin and nature of the leucocytes in general. By special staining methods he has been able to demonstrate the presence of granulations in the lymphocytes which are characteristic in their staining reactions, arrangement, and form. The technique is as follows: The smears are made in the usual way and placed for twelve hours in a ten to per cent. solution of formalin Müller, and are then put for twelve hours longer into plain Müller's fluid. At the conclusion of this time they are rinsed in plain and then in distilled water, and stained for 1 to 2 minutes for from sixty minutes, being protected from light. They are again rinsed and stained in Ehrlich's acid water and toluidin solution. This is made adding twenty parts of acid fuchsin to one hundred parts of a cold, saturated, filtered solution of toluin in distilled water. The cover glass covered with the stain is warmed until it steams, and after cooling is counterstained with a solution containing one part of saturated alcoholic solution of picric acid and seven parts of 20 per cent. alcohol. The preparation is decolorized with absolute alcohol as soon as it shows a yellow tinge and is then ready for mounting. All the leucocytes except basophiles should show granules, the latter cells exhibiting only colorless vacuoles corresponding to granules. The granules in the eosinophiles are black, those of the neutrophiles pale, brownish red. The lymphocytes exhibit granulations intermediate in size, and yellowish red in color. They usually are clustered about the nucleus and are not very numerous. The nuclei of the lymphocytes are stained a light, sepia brown, whereas those of the leucocytes are a dark, dirty, yellowish red.

**The Fatigue Toxin and its Antitoxin.**—Weichardt contributes a further communication on this subject, in which he refers to a better method of fatiguing the experiment animals. The guinea pig to be used is placed in a bell jar into which pure carbonic oxide is admitted. As soon as it becomes comatose its entire musculature is fatigued by faradization in the rarefied air of the bell jar, the current used being extremely weak, so that all painful contractions are avoided. When death has occurred owing to the fatigue autointoxication, the current is for a time applied in much increased strength. The precautions necessary in obtaining the toxin are very great and require intricate manipulations, as oxidation deprives the toxin of its virulence. The author has found that the reverse is also true, viz., that by the use of reducing agents it is possible to increase the amount of toxin, and that it is also possible to obtain toxic bodies from the muscle juice of unfatigued animals. Reduction toxins may in this way also be obtained from other varieties of albumin, such as placental albumin, that of the brain, from pollen, and even from egg albumen. The related nature of these bodies is shown by the fact that the fatigue antitoxin to a greater or less degree neutralizes all of them. Animals can be rendered markedly resistant to fatigue by giving them fatigue antitoxin by mouth and then immunizing them by injections of fatigue toxin.

**The Treatment of Goiter with the Röntgen Rays.**—Stegman describes two cases in which improvement followed the application of the Röntgen rays to thyroid enlargements. The first case was that of a woman of fifty-two, who was being subjected to radiotherapy for some supraclavicular mestastases of a carcinoma of the breast which had been removed by operation. At the same time a parenchymatous goiter of considerable size was also exposed to the action of the rays. After the sixth session the enlarged glands could no longer be palpated and the goiter had diminished in size by about a quarter of its volume. The second patient was a girl of twenty-one, with a large, soft parenchymatous goiter. After only two radiations the circumference of the neck decreased from 39.8 cm. to 36cm., and the previously existing dyspnea was relieved. In view of these good results the author urges further trial of the method in order to establish its value by testing it on a large number of cases.

*Deutsche medizinische Wochenschrift, June* 29, 1905.

**Demonstration and Occurrence of the Spirochæta Pallida in Syphilis.**—Herxheimer and Hübner have found that in place of Giemsa's azureosin stain a simpler method serves equally well for the demonstration of the spirochæta pallida in the secretions of syphilitics. A 1-1000 solution of either Nile blue B R, or of Capri blue, allowed to act on a smear for 16-24 hours gives satisfactory results, the organisms in the former case being stained a dark blue, and in the latter, gray. In making the examinations it was found that considerable practice was necessary to recognize the almost transparent spirochæta, but out of fifteen cases which clinically were undoubtedly syphilitic, the organism was found in all but one, though frequently only after hours of search. In two doubtful cases the organism was not found. In two instances the observers were able to demonstrate a single spirochæta in sections of tissue. In order to disprove the allegation which has been made to the effect that the spirochæte were organisms developing in the staining fluids the authors searched through a series of covers on which the solution had been allowed to dry, but without finding any spirochæte. Motile spirochetæ were also discovered in hanging drop preparations.

**Observations on the Staining of the Spirochæta Pallida.**—Giemsa gives the formula for a new solution which he considers the best yet discovered for staining protozoa and spirochætes. One of its advantages is that it contains an excess of the basic dye, so that its keeping qualities are assured even in tropical climates, and precipitation of the dye on mixture with water is prevented. The composition of the stain is as follows: Azur II eosin, 3o; azur II, 80; glycerin (chemically pure), 250g.; methyl alcohol, 250g. The smears are made very thin, and after drying are fixed for fifteen to twenty minutes in absolute alcohol and dried with blotting paper. The stain is then diluted in the pro-

portion of about one drop to the c.c. of water, and is then immediately poured over the preparation. After ten to fifteen minutes it is washed off with a stream of water, the preparation is dried, and is then ready for mounting. For some purposes, including the staining of the spirochæta, it is advisable to add to the water before diluting the stain a few drops of a 1-1000 solution of potassium carbonate. Overstained preparations may be decolorized by placing for one to five minutes in distilled water. Schaudinn's spirochæta is distinctly stained by this solution in one to five minutes, but the best results are obtained at the end of one hour.

**The Diagnosis and Treatment of Chronic Appendicitis.**—Albu, who believes that greater discrimination should be applied in selecting cases of appendicular disease for operation, says that although it is possible for an acute appendicitis to terminate in complete cure without leaving any permanent traces, still in most cases a chronic inflammatory process persists. This may take one of two forms. In the first there are numerous acute recurrences of varying intensity, and with variable intervals between them. The patients are usually fairly well during the intervals, or suffer only from slight disturbances, among which obstinate constipation is prominent. A smaller group comprises those cases in which the symptoms never wholly subside after the acute attack, so that although the patients may be able to return to their work, they are never quite well again. There is, however, a third class of cases in which there never was any acute attack, and the symptoms develop insidiously, gradually increasing, or remaining stationary for a time, so that for years the patients are more or less conscious of some obscure trouble which is difficult to recognize. The question of operation is a very difficult one to decide in such cases, but much can be accomplished toward rendering the condition quiescent by appropriate treatment. Measures to be recommended are, protracted and complete bodily rest, in some cases rest in bed for a considerable length of time, with or without warm applications to the abdomen; careful regulation of the bowels through a vegetable diet, enemata, etc.; suppositories of belladonna two or three times a day; the use of warm baths of various sorts, and, finally, a course of treatment at some suitable watering place. The author cites several instances in which the appendix was removed or the diagnosis of appendicitis made in cases that were later found to be due to such conditions as visceral neuralgia, spastic constipation, flatulent colic, etc. He also describes two cases of genuine chronic appendicitis which were rendered latent by the therapeutic measures indicated.

*French and Italian Journals.*

**Tuberculous Cervical Adenitis Favorably Treated by the X-Rays.**—Jean Ferrand and Krouchkoll, in describing this case, state that they were among the first to use the *x*-ray in cases of tuberculous cervical adenitis. Before publishing this case, they have allowed nearly a year to pass since the beginning of the treatment, in order to prove the persistence of the good results. The patient has been out of the hospital for five months, and she has been able to resume her work. The older treatment by arsenic and iodides was instituted at first, after the diagnosis had been made, but was not followed by recovery. The first treatment by the *x*-ray was given on August 20th, 1904, and the writers observed the improvement from day to day after this treatment was begun. One of them also treated other cases of this disease in the same manner, and the result has always been favorable. Even two cases of suppurative adenitis have improved under the *x*-ray. In the patient here reported, the cervical tumors have been completely transformed. The writers think that hard tubes should be employed; the sittings should be short—ten minutes for the maximum. The treatment should be interrupted if pigmentation appears. They believe that this treatment should be tried in all cases of chronic tuberculous cervical adenitis, for all other methods, both medical and surgical, are uncertain.—*Gazette des Hôpitaux Civils et Militaires*, June 20, 1905.

**Scopolamine and Chloroform Associated in Producing Anesthesia.**—Walter is employing the following proceeding: He gives an injection of one milligram of scopolamine and one centigram of morphine an hour before operation. This combination of drugs causes sleep, which persists up to the time that chloroform is given. In case of the adult, there is no inconvenience attaching to this method, and there are various advantages. The patient has no apprehension concerning the operation. Sleep continues with small doses of chloroform; the respiration is regular and quiet, and sleep continues after the operation. The writer has not observed the tendency to hemorrhages in the use of scopolamine, which has been noted by some writers; neither has he seen any contraction of the abdominal walls, for he has used a smaller dose of the drug than previous experimenters. He believes that vomiting depends upon individual susceptibility. He notes, however, that the combined use of scopolamine and chloroform deprives one of a guide during anesthesia, for the play of the pupil which is dilated does not give its customary indications of the effect of chloroform.—*Le Bulletin Médical*, June 24, 1905.

**Recurrent Dislocations of the Shoulder.**—Legueu reports the history of a young epileptic, seventeen years old, who in his falls dislocated his left shoulder several times. Legueu opened the articulation, exposed the capsule, and incised it. Bloody liquid flowed out from this wound, and the classic lesions of extracoracoid dislocation were found. The dislocation was reduced, and the wound was closed by sutures in three planes. The sutures were so disposed that they held the humeral head well in the capsule; but the epileptic crises increased, and, in spite of all precautions, there was recurrence of the dislocation, which was reduced by Kocher's method. This case shows that the operation of opening the capsule is not a sure method for the prevention of recurrences of dislocation in epileptics.—*Gazette des Hôpitaux Civils et Militaires*, June 17, 1905.

**Absorption of Iodine by Electric Cataphoresis.**—Raffaele Pisani and Raffaele Paladine made experiments to determine whether iodine was hastened in its absorption by the use of electricity, and which pole was of most use. They first determined, by examination of the excreta, that iodine was not absorbed through the unbroken skin, since none was eliminated. They used a saturated solution of iodide of potash, or of iodine, to wet the electrodes, and found that in dogs the iodine is absorbed at the cathode alone. The absorption and elimination of the iodine begins at once, after a few minutes, and elimination continues two to three days. With currents of high intensity and long duration, the elimination continues longest. The effects of the iodine vary with the weight and size of the dog. The absorption is small when currents of high intensity are not used.—*Giornale di Elettricità Medica*, May and June, 1905.

**The Paravertebral Triangle of Grecco.**—A. Plessi has observed the existence of the paravertebral triangle of Grecco in cases of pleurisy with effusion. This triangle consists of an area, triangular in shape, that constitutes a focus of dullness on the posterior surface of the thorax opposite to the location of the effusion, which is modified in its intensity of dullness by decubitus, amount of liquid and respiratory acts, and is mose noticeable on the right, with a diminution of vesicular murmur. The author tried to find this triangle in cases of pleurisy with effusion, and to study its phenomena. He believes that it always exists, and is generally easy to find. When respiratory murmur is absent over the affected area, this is also marked over the paravertebral triangle. Fremitus is much diminished externally, and abolished at the maiden line. Over the external zone crepitant râles are heard.—*La Riforma Medica*, June 24, 1905.

**Bacteriological Researches on Measles.**—Agostino Borini gives us the results of his researches as to the germ that causes measles. He made cultures from the blood, bronchial secretion, and conjunctival secretion from babies sick with a severe form of measles. The blood was obtained at the moment when the fever was at its height, and the exanthema most marked. He found a small bacillus, thin, mostly found in groups of two, length 0.7 , coloring with difficulty with analine colors, not resistant to Gram; the development was always sparse. It did not develop on gelatine; in agar with defibrinated blood; after thirty-six hours, there were punctiform, transparent, gray-yellow colonies, which slowly became confluent. On broth with blood the development was more abundant. The microorganism was hard to preserve, becoming negative after two or three cultures. Injections into the trachea of dogs of a fresh culture causes death in from three to six days. Autopsy showed small foci of bronchopneumonia; other organs normal. Endopleural, endoperitoneal, and splenic injections caused death without lesions, a few bacilli being found in the blood.—*La Riforma Medica*, June 24, 1905.

**Vesical and Urethral Calculi in Children.**—Franco Crosti tells us that vesical calculi are quite frequent among infants and children. After puberty they decrease in frequency. They are more common among the poorer classes on account of the preponderance of vegetable foods. The principle symptoms are pain, often very severe and causing the child to masturbate for relief; slight hematuria, and disturbances of urination, such as frequent micturition, incontinence rebellious to treatment, and sudden stopping of the flow during the act of micturition. Calculi are usually single, free, and occupy the fundus. The condition simulates tuberculosis of the bladder, and a bacteriological examination is needed to clear up the diagnosis. There should be an examination of the bladder with the sound under anesthesia before the diagnosis is established.—*Gazzetta Medica Lombarda*, May 20, 1905.

# Book Reviews.

The Historical Relations of Medicine and Surgery to the End of the Sixteenth Century. An Address Delivered at the St. Louis Congress in 1904. By T. Clifford Allbutt, M.A., M.D., Hon. M.D. (Dubl.), Hon. LL.D. (Glasgow), Hon. D.S.C. (Oxf. and Vict.), F.R.C.P., F.R.S., F.L.S., F.S.A. Regius Professor of Physics in the University of Cambridge, Fellow of Gonville and Caius College, Hon. Fellow Royal College of Physicians of Ireland, etc. London: Macmillan & Co., Limited; New York: The Macmillan Company, 1905.

In this gracefully written essay the progress of medicine is outlined from its inception in the early schools of Greece, to the end of the sixteenth century. At first, having a common origin, medicine and surgery progressed side by side, but finally in the days of Avicenna the separation came and the practitioners of each branch began to follow different paths, to the great detriment of the art as a whole. The object of the address is to emphasize the evil of the factitious division of practice into medicine and surgery, not by personal choice on natural lines, but through a survival of medieval rules, and its perusal is both interesting and convincing.

Lehrbuch der inneren Medizin, für Arzte und Studierende. Von Dr. med. Georg Klemperer, Universitäts Professor in Berlin. Erster Band. Berlin: August Hirschwald, 1905.

In his preface, Klemperer tells us that the present textbook of medicine was begun fifteen years ago, and that it was undertaken with the hope of replacing the classical work of Niemeyer, which for thirty years occupied so prominent a place in medical literature. The success of the author's handbook of physical diagnosis attests his ability as a teacher, and the foundation of the present textbook was formed by his lectures delivered since 1890, in the University of Berlin. The fact that Klemperer has been as active in private practice as in academic work has enabled him to give his book a practical tone that is often conspicuously absent in the writings of German authors. We accordingly find that treatment in general and in its specific applications is discussed with a much greater attention to detail than one is accustomed to find in German books, and in this perhaps lies its chief claim to distinction from other works of its class. The textbook when completed will consist of three volumes, of which, the second, is promised for the latter part of this year, and the third for the early months of the next. The present volume is devoted to diseases of the digestive tract, of the urinary organs, and of the male genitals. Numerous formulæ, the maximum doses of the German pharmacopeia, a discussion of balneotherapy and allied topics, and a short section on medical technique are included in an appendix. The strong personality of the writer appears distinctly throughout the entire book, and adds much to its interest and value.

The Eye, Mind, Energy, and Matter. By Chalmers Prentice, M.D. Chicago: Published by the author, 1905.

This book contains a motto, a fable, and seventeen chapters; about one-half of it deals with the eye. From the other half we glean: that plants think; that "in the union of health adjuncts, and the absence of pessimism, there is no such thing as incurable disease"; that drunkenness is a nervous disorder, and can be cured by the use of eyeglasses. The fog cure for nervousness is also mentioned.

A System of Clinical Medicine. Dealing with the Diagnosis, Prognosis and Treatment of Disease. For Students and Practitioners. By Thomas D. Savill, M.D., London. Physician to the West End Hospital for Diseases of the Nervous System; Physician to St. John's Hospital for Diseases of the Skin, London; Formerly Medical Superintendent of the Paddington Infirmary; Medical Officer of the Paddington Workhouse, and Post-Graduate Lecturer to the London Post-Graduate Association; Assistant Physician and Pathologist to the West London Hospital; Examiner in Medicine and Clinical Medicine in the University of Glasgow; and Medical Officer to the Royal Commission on Vaccination. Vol. II. Certain General Disorders; Diseases of the Skin and Nervous System. Philadelphia: P. Blakiston's Son & Co.; London: J. & A. Churchill, 1905.

In the second and concluding volume of this system of medicine the author carries out the same method with which he started, i. e. the various disorders are approached from the symptomatic side, in other words, imitating the mental processes of the physician as he obtains the history and makes the physical examination of his patient. The first portion of the volume is given to the consideration of general debility, pallor, and emaciation, and Dr. Savill not only states the possible causes, but also their relative probability of existence. Then follows the symptomatology of the extremities, together with prognosis, treatment, etc. Sixty-five pages are allotted to diseases of the skin, and a few plates are incorporated. Ideally all diseases of the skin should be illustrated with colored plates, but in a work of this sort it would, of course, be out of place. The major and concluding part of the work appertains alone to nervous diseases, and a shorter chapter on clinical bacteriology and the examination of pathological fluids.

In the section on neurology the author's method is particularly helpful in diagnosticating these obscure lesions, for, starting with a few symptoms, he is taught to consider the possibilities, and then to make an exhaustive examination, which will differentiate them.

The book is thoroughly scientific, extremely helpful and thorough, and will enable the reader to approach his subject in a fresh and eminently practical manner.

The Book of Prescriptions (Beasley). Containing a complete set of prescriptions illustrating the employment of the materia medica in general use; comprising also notes on the pharmacology and therapeutics of the principal drugs and the doses of their preparations according to the Imperial and metric systems, with an index of diseases and remedies. Rewritten by E. W. Lucas, F.I.C., F.C.S., Pharmaceutical Chemist, Late Examiner to the Pharmaceutical Society of Great Britain, Author of "Practical Pharmacy." With an introduction by Arthur Latham, M.A., M.D., F.R.C.P. Senior Assistant Physician at St. George's Hospital, Assistant Physician at the Brompton Hospital for Consumption. Eighth Edition. Philadelphia: P. Blakiston's Son & Co., 1905.

The eighth edition of this standard formulary has been brought up to date and contains short descriptions of most of the more important of the newer remedies. The number of prescriptions is very large and should prove useful to young practitioners, though the English origin of the book may cause some embarrassment to those not well grounded in the United States Pharmacopeia. A comprehensive index of diseases is appended for reference in emergencies.

Dental Surgery for Medical Practitioners and Students of Medicine. By A. W. Barrett, M.B. (London), M.R.C.S., L.D.S.E., Etc. Fourth Edition. Philadelphia: P. Blakiston's Son & Co., 1905.

This book presents in concise form what the author has been teaching to medical students at the London Hospital; the aim being to give sufficient practical information for the ordinary needs of the student or practitioner. There are chapters on dentition, abnormalities and irregularities in position and development, caries, toothache, injuries, anesthetics, etc. Operative dentistry, including fillings and false teeth, is not discussed, being more within the scope of the dental specialist. The little book affords a fair general knowledge of dentistry for the medical man who is often called upon to recognize or give advice with respect to various dental conditions.

Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. Authorized American Edition Translated under the Direction of Boardman Reed, M.D., Professor of Diseases of the Gastrointestinal Tract, Hygiene, and Climatology, Department of Medicine, Temple College; Physician to the Samaritan Hospital, Philadelphia, Etc. Part VI. Drink Restriction (Thirst-cures), Particularly in Obesity. By Professor Carl von Noorden and Dr. Hugo Solomon. New York: E. B. Treat & Co., 1905.

The authors in this little monograph continue the discussion relative to metabolism and nutrition, which was begun and kept up in the five preceding volumes. The well-known empirical thirst cures of Oertel and Schweninger are considered, and also their supposed reasons for existence, which were in part true, and in part false. The older experiments are then given, such as had bearing on the subject in hand, and these are followed by the highly accurate and painstaking investigations of the authors, which clear up very satisfactorily the rational basis upon which success is founded. Although the truths seem simple, they are all the more of fundamental importance.

Saunders' Pocket Medical Formulary. By William M. Powell, M.D., author of "Essentials of Diseases of Children"; Member of Philadelphia Pathological Society. With an Appendix containing Posological Table, Formulæ and Doses for Hypodermic Medication, Poisons and their Antidotes, Diameters of the Female Pelvis and Fetal Head, Obstetrical Table, Diet-list, Materials and Drugs used in Antiseptic Surgery, Treatment of Asphyxia from Drowning, Surgical Remembrancer, Tables of Incompatibles, Eruptive Fevers, etc. Seventh edition, thoroughly revised and enlarged. Philadelphia and London: W. B. Saunders & Co., 1905.

The seventh edition of this useful collection of formulæ requires little in the way of commendation. Its title page indicates its scope, and the several departments are all satisfactory in matter and arrangement, so that the little volume should prove very serviceable to those who feel the need of such a reminder.

# Society Reports.

## AMERICAN MEDICAL ASSOCIATION.

*Fifty-sixth Annual Meeting Held in Portland, Oregon, July 11, 12, 13 and 14, 1905.*

(*Continued from page 119.*)

(Special Report by Telegraph and Mail to the MEDICAL RECORD.)

### GENERAL SESSION.

*Second Day—Wednesday, July 12.*

**Oration on State Medicine.**—Dr. GEORGE BLUMER of San Francisco delivered this oration, taking as his subject, "Influence Which the Acquisition of Tropical Territory by the United States Has Had and Is Likely to Have on American Medicine." (See page 125.)

**Memorial to the Late Dr. N. S. Davis.**—Dr. HENRY O. MARCY of Boston then pronounced a eulogy on the late Dr. Nathan S. Davis.

### HOUSE OF DELEGATES.

*Fourth Day—Thursday, July 13.*

**The Work of Organization.**—Dr. PHILIP MILLS JONES of California introduced a resolution approving of the work of organization of subordinate societies by Dr. McCormack, and requesting that the work be continued.

Dr. J. N. MCCORMACK spoke in answer to the resolution, explaining the difficulties he had encountered in this work. Many men approached regarding the project were suspicious, looking for ulterior motives in the organizer. He had, however, met with a measure of success, and would consent to continue the work for another year.

The resolution of Dr. Jones was adopted by a unanimous vote.

**Election of Officers.**—The following officers were elected: *President,* Dr. William J. Mayo of Rochester, Minn.; *Vice-Presidents,* Drs. Walter Wyman, Surgeon-General U. S. Public Health and Marine Hospital Service, K. A. J. Mackenzie of Oregon, E. S. Talbot of Illinois, and E. D. Martin of Pennsylvania; *Secretary,* Dr. George H. Simmons of Chicago; *Treasurer,* Dr. Frank Billings of Chicago; *Trustees,* Drs. E. E. Montgomery, A. L. Wright, and H. L. E. Johnson; *Members of Council,* Drs. P. M. Foshay, reappointed, and W. S. Foster, elected in place of Dr. Wiggin, resigned; *Orator in Medicine,* Dr. F. C. Shuttuck of Boston; *Orator in Surgery,* Dr. Joseph D. Bryant of New York; *Orator in State Medicine,* Dr. W. H. Sanders of Montgomery, Ala. The next place of meeting will be Boston, the date to be determined later by the officers.

**The Davis Memorial.**—Dr. HENRY O. MARCY of Boston introduced a resolution calling for subscriptions to a monument to be erected as a memorial to the late Dr. Nathan S. Davis, and made an initial subscription of one hundred dollars.

**Reports of Committees.**—The report of the Committee on Section Work was presented and approved. The Committee on the President's Address made a report approving of the recommendation made by the President in his address. The Committees on Amendments, on the By-Laws, on Public Health, and on Minutes also reported, the recommendation of the latter being promptly tabled. On motion, the copy of a bill to be presented to Congress granting a pension to the widow of the late Surgeon-General Harris was referred to the Committee on Legislation.

Dr. J. N. MCCORMACK proposed a vote of thanks to the profession and people of Portland for many courtesies and to the officers of the Association for their very efficient work in relation to the present meeting.

A resolution was introduced from the Section on Laryngology, asking that copies of the section reports be sent free to members instead of being sold for one dollar.

A letter was read from a physician of Porto Rico, asking for recognition of the medical association of the island.

### SECTION ON DISEASES OF CHILDREN.

*First Day—Tuesday, July 11, 1905.*

CHAIRMAN, DR. JOHN LOVETT MORSE, OF BOSTON.

**The Teaching of Pediatries.**—Dr. JOHN LOVETT MORSE in this, the Chairman's, address gave a description of the course of study at the Harvard Medical School. Pediatrics is taught as a part of the required course in the third year, and as an elective in the fourth year. The third class is divided into sections of two or three men, which sections are assigned to different departments so that no instructor has more than six students at a time. The last two hours of each morning are devoted to section teaching, each exercise lasting from 1½ to 2 hours. The fourth year comprises 1,000 hours, or eight courses of 125 hours. A course means all day for one month, or one-half day for two months. The Department of Pediatrics at Harvard controls the medical wards of the Children's and the Infants' Hospitals, as the nomination of the visiting physicians to these hospitals is in the hands of Harvard University. Instruction in the third year is given to the whole class by lectures, etc., while special exercises are given on infant feeding and gastrointestinal diseases. The entire teaching system at Harvard was described in detail. The author deemed recitations of little use, but attached most importance to case teaching. The greatest obstacle to section teaching, he observed, was in the number of instructors required and the entailed expense. The teaching of pediatrics, however, he believed would never be ideal until the heads of departments devoted their entire time and energy to their teaching. Higher salaries must be paid to enable them to do this. Chairs, therefore, must be endowed, and to see that this was done rested with the public.

**A Plea for National and Local Boards of School Hygiene.**—Dr. ALICE M. SMITH of Tacoma said that the altruistic ideal is the noblest conception of man, and that preventive medicine is its most practical application. In consideration of the enormous annual loss to the Government and to society through disease it is self-evident that it is the duty of the Government to protect its people from the peril of preventable diseases. Because of the relation of school hygiene to the science of human development and to preventive medicine Dr. Smith stated that there was no subject of such vital importance to mankind as the education and the hygiene of the developing child, and she considered it imperative that a better system of school hygiene be instituted to the end that children may receive their "absolute civil rights"—the right of personal security and protection from the Government against avoidable evils. The defects of the present system were pointed out to be: Ignorance of the average school board of technical and scientific knowledge as applied to the science of human development and progress; phenomenal extravagance incident to this ignorance and many separate managements; want of organization; lack of proper medical supervision of school hygiene; ignorance of parents and teachers of the requirements of children for the best physical development. The changes essential to a better system were pointed out to be an elimination of those elements inimical to the social welfare and such improvements as may be expedient—in short, the practical application of preventive medicine. Dr. Smith suggested that there should be a National Board of School Hygiene and Preventive Medicine, composed of representative, non-partisan physicians. It should be the duty of this Board to investigate school hygiene, education in its relation to human development, and into the causes and means of prevention of contagious and infectious diseases and of degeneracy and crime, etc. In the opinion of the author, there should also be a State Board of School Hygiene and Preventive Medicine, and the duties of this board were also outlined. Another important feature of this system should be the establishment of a complete federation of all boards of school hygiene and preventive medicine in the State with the State Board;

with the local, State, and national boards of health, and with the State and national boards of education.

Dr. C. F. Wahrer of Fort Madison, Iowa, thought the paper particularly timely. In his opinion the question arose regarding responsibility for our fellow man. Legislatures more readily introduced a river and harbor bill than one to appropriate funds for the schemes advanced by the essayist. This he believed was because they were importuned to do it. In the same manner physicians should carry out the same plan when needing money for the betterment of conditions in general.

Dr. Arthur W. Fairbanks of Boston agreed with Dr Smith that there was tremendous opportunity for pioneer work in schools, and referred incidentally to the fact that he was from the city which first introduced medical influence in the schools. While, as one of the physicians appointed by the Board of Health, he could tell the teachers what should be done with a child, he had no power whatever over the hygiene of the school, no power to regulate the light as it strikes the blackboard and no power over the physical exercises, and thus their hands were tied. This power he would have greatly extended, and not kept, as now, out of the control of the boards of health.

Dr. Wahrer thought there should be a publication committee appointed in every medical society and in every medical section who will give to the Associated Press the opinion of such medical societies on topics discussed, believing that the people of the United States will read the press when they will not read medical journals.

Dr. Garrison of Illinois thought that every physician should feel responsible for the immediate family which he attends. In this way there would be brought about an educated laity.

Dr. McGavin of Portland referred to the readiness with which the laity accept teaching upon medical and hygienic lines. She had noticed this readiness also in the Chinese in the city of Portland.

Dr. Smith, in closing, said that in the financial success of the system advanced benefit would accrue to the physicians in giving them a larger field for work. With the establishment of a sanitary board at Washington from which the State boards could secure help, she believed there would be saved to the Government millions of dollars.

**Rules For the Care of Young Infants in Public Institutions.**—Dr. H. M. McClanahan of Omaha said that it had long been recognized that the care of infants in public institutions presented peculiar difficulties, and that the mortality was greater than in private practice. He had been attending physician at a certain institution in 1901-'02, but was without authority. In 1903-'04 he had been given authority to employ a head nurse in the infants' ward and enforce certain rules, the first of which was with regard to the soiled napkins. The nurse was required to remove the napkin and not lay it out of her hands until it was deposited in a bucket prepared for the purpose. He then required the nurse to disinfect her hands immediately afterward. Another point of his paper was that a nurse should prepare the food for a specified time. Any error, therefore, in its preparation could be easily traced. Insufficient air space was compensated for by using another ward in the daytime. While this plan is not ideal, it has been found much better than allowing the infants to remain in one ward continually. The wards are fumigated twice a week with formaldehyde candles. The windows are closed and the keyholes plugged for four hours, and thorough ventilation is thus necessary. An infant presenting any symptoms of sickness is isolated at once. Last summer there was but one child of all who were in the institution on the first day of June who developed gastro-intestinal disease.

Dr John C. Cook of Chicago considered the education of the nurses for the care of children one of the most important and perhaps one of the most neglected things in the training schools of the United States. Following an epidemic of pneumonia in an institution with which he was connected he had had the beds taken up until each child had seven hundred cubic feet of air space. To accomplish this the children were put into the corridors. The nurses who gave medicines and foods were not allowed to remove the napkins. Nurse girls took charge of the napkins and cleansed the babies. He thought the amount of damage done to babies by the unclean hands of nurses was not appreciated. Education of the nurses along these lines he believed would result in great good to the general public.

Dr. Arthur W. Fairbanks of Boston referred to the occurrence of a severe form of bowel infection with reinfection. Studies of the subject made him feel that the nurses' hands had something to do with it. Thorough cleansing of the hands with the coincident exclusion of flies from the hospital wards had brought about results beyond his expectation.

Dr. Alice M. Smith of Tacoma referred to the habit of mothers and nurses of putting things into their mouths and transferring them to the child's mouth. The fumigation of the rooms and the washing of the floors in places where children were congregated were considered of great importance.

Dr. Lindsay of Colorado thought the only hope lay in educating the nurses, who in turn would educate the mother upon lines pertaining to the child's hygiene and health.

Dr. Wahrer thought the physician could not be too insistent in teaching these rules.

Dr. McClanahan closed the discussion by emphasizing some of the points in his paper.

*Second Day—Wednesday, July 12.*

Dr. A. C. Cotton of Chicago was appointed upon the Executive Committee to take the place of Dr. C. G. Kerley of New York City.

**Amaurotic Family Idiocy.**—Dr. A. C. Cotton of Chicago presented a report of three cases of this disease with a picture of the eye ground findings. He said the disease was of special interest to pediatrists because of the infrequency with which it has been reported, the probability of overlooking it, and the necessity of a thorough eye ground demonstration to confirm diagnosis. It is of peculiar interest to the ophthalmologist on account of the pathology of the eye ground. It is a fatal disease, commencing in the youngest years of life. The earliest case was in a child two months and a half old. There is a marked racial peculiarity of the disease, most of the cases being of Jewish children. He showed one picture of a healthy child of eleven months without any signs of abnormality. The hearing remains hyperacute. There was deglutition in every one of his cases. He exhibited the chart of Dr. Mortimer Frank, containing all the cases reported up to July 1, 1905. There were 54 cases with complete histories; 20 additional cases were alluded to; 12 post mortems have been performed altogether. Twenty-seven cases were in Jews, 6 in Gentiles, and in 21 there was no parentage given. In 15 cases nystagmus was present. The youngest reported case was under four months; the oldest three and three-quarters years. He gave a condensed review of the literature, and made some observations regarding the effects of food and digestive disturbances on the symptoms.

Dr. John Lovett Morse of Boston said he had had the opportunity of seeing five cases of this disease, one of which is still under observation. The striking thing about them all is the flaccid paralysis which is noticed before blindness. He said that the eye ground was so characteristic that it does not require an ophthalmologist to recognize it. The attitude of the child in convulsions was exactly that as described by Dr. Cotton. The interference with deglutition he thought was a matter to which sufficient attention had not been called. In the last case that he had seen the child had to be fed with a stomach tube.

Dr. Cotton, in closing, said that he had analyzed the

mother's milk repeatedly because she was nursing a baby two or three months of age, and had found the milk in good condition. During the nursing of a second child examination of the milk showed a marked paucity of fat, and this was the condition during the nursing of a third child. Dr. Cotton believed that there need be no controversy between Hirsh's suggestion that the baby acquires the disease from something in the mother's milk, and the theory advanced by Sachs. If the disease is due to heredity, it would seem that each child of the same mother would be affected.

**The Prevention of Summer Diarrhea.**—Dr. Maurice Ostheimer of Philadelphia said that summer diarrheas are due chiefly to two causes—unclean food and hot weather. While bacteria are undoubtedly the exciting cause, they seem unable to act deleteriously until there is lessened vital resistance. Upon the appearance of gastro-intestinal derangement he would stop all milk at once and give barley water or whey. He advised the distribution of pamphlets of instructions to mothers for the care and feeding of infants during the heated term. Of the fifteen largest cities of the United States, such booklets are distributed but by nine. Four cities have them printed in several languages. He suggested the advisability of having special "milk" courses in public schools, medical schools and hospitals; and, for the supply of "clean" milk to rich and poor alike, he advocated the acquirement by every large city of a dairy in the outskirts of the city to be under the guidance of a milk commission, such dairy to come under the jurisdiction of the municipal health department. Dr. Ostheimer described a sample pamphlet of instructions for the care and feeding of young children during the hot weather. Directions in this are given regarding clothing, bathing, fresh air, sleep, soiled napkins, flies, breast-feeding, and bottle-feeding. A table was given for the method of feeding of the baby, and the child should be weighed every two weeks. Should it fail to gain at the end of two weeks, clean cream may be added, beginning with a teaspoonful to each bottle, gradually increasing according to the advice of the physician. Directions were also given in regard to weaning, and to feeding after the first year.

Dr. C. F. Wahrer of Fort Madison said that every case of summer diarrhea was a case of itself, and that there were many known and unknown factors. He said there were two reasons for the greater number of cases during the summer—one being because the heat increases putrefactive changes, and the second the disturbance of the nervous system caused by the heat. He felt that much could be gained by attention to the sanitation of the lives of the mothers.

Dr. Kate Lindsay of Boulder referred to the ignorance in the farming district, and, while she agreed that it was well to educate the people of the slums, those in the farming districts should be taught regarding the care of the milk for the child. She gave an instance of a farmer who had been very angry because his best mare had been driven and overheated, while at the same time his wife, with a girl of sixteen, had done all the work of a large family while she was nursing a child.

Dr. G. Blumer of San Francisco called attention to the fact that cases of summer diarrhea in that city always occurred after their occasional hot spells.

Dr. Arthur W. Fairbanks inquired how long Dr. Ostheimer kept the children on a cereal mixture, and what the indications were for taking the child off of the milk mixture—whether it was fever or general septic signs.

Dr. A. C. Cotton of Chicago appreciated the idea of reaching the laity by means of circulars, and believed that the health department has had some of its best successes through the pamphlets issued to the mothers. He would have them placed in a conspicuous place, framed if necessary, and the mothers taught to look to them constantly. He called particular attention to the slight regurgitation, the result of too rapid feeding, which is usually the first sign of trouble. This the mother should be taught to watch.

Dr. Wells of North Yakima asked what nourishment Dr. Ostheimer would give after taking the child off of milk. He is in the habit of giving panopeptin with a few drops of brandy, and inquired whether the brandy had been injurious to the author's cases.

Dr. John Lovett Morse objected to the title, "summer diarrhea," and thought the expression should be diarrhea in the summer."

Dr. Ostheimer, in closing, said that the length of time he kept the baby on the barley water depended upon the symptoms. He would add panopeptin or brandy, and would fear no bad results. At the first sign of gastro-intestinal derangement he would stop the milk.

**A Study of Fifteen Cases of Summer Diarrhea in Children.**—Dr. John C. Cook of Chicago presented these cases selected from 250 cases of children's diseases at the Jackson Park Sanitarium during July and August of 1904. The cases were divided into (1) a class comprising 11 cases of a mild type, the records of which serve as a standard of comparison for estimating the value of the findings in the remaining cases, and (2) a class comprising four fatal cases of special interest because of the bacteriological and microscopical findings during the clinical course and post mortem. The findings of the two classes were given. One bacteriological finding in the stools of the last of the severe cases, a female aged 7½ months, was a red pigmenting bacillus of the colon group that developed a red pigment so rapidly that the feces and mucous secretions were stained blood red. No blood, however, was found upon microscopical examination. To the author it seems probable that some of the well-known pathogenic organisms gain entrance to the general circulation through lesions in the gastrointestinal tract, give rise to septicemia and are the immediate cause of death; that these atria of infection are produced by the local action of less toxic microorganisms as staphylococcus, colon bacillus, yeasts, and thrush fungus; and that the toxines which are generated by the saphrophytic action of all of the microorganisms in the intestines tend both to lower the resistance of the child and mask the symptoms of the specific intoxication. It is further apparent, in his opinion, that the increased frequency of vomiting and bowel movement is more often due to the reflex action of septicemia and sapremia than to direct intestinal irritation. If the conditions of sepsis and sapremia be true, Dr. Cook believes that the problem of treatment resolves itself into a question of maintaining the general resistance of the child and neutralizing the specific intoxication.

Dr. Michael of Chicago described the method employed by Drs. Cook, Weaver, and herself in collecting the stools in summer diarrhea.

Dr. Fairbanks of Boston referred to the red pigmenting bacillus mentioned by Dr. Cook, and felt that this explained a puzzling experience he had encountered in his own service.

Dr. Cook, in closing, said he believed the red pigmenting bacillus to be of the colon group. He had found no literature on the subject. It had occurred twice in their studies, and the quantity of blood or stain was sufficient to indicate a hemorrhage of the bowels. In the case of typhoid fever mentioned, the vomiting and the bowel movements were likely to occur together.

---

## SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

*First Day—Tuesday, July 11.*

Dr. Charles L. Bonifield in the Chair.

**Chairman's Address.**—Dr. Bonifield called attention to the desirability of having a permanent secretary who should be allowed traveling and incidental expenses, and said that papers should be read by men of more than local reputation, and suggested that the name of the section be changed to Section on Obstetrics, Diseases of Women, and Abdominal

Surgery. He then reviewed briefly the subjects which have interested obstetricians and gynecologists during the year, such as retrodisplacement of the uterus, a condition in which, he said, surgical treatment is not always either indicated or desirable; cancer of the uterus, in which operation should be done always—just how radical that should be to depend on local and systemic conditions and the skill of the operator—the operation not to be too severe for the patient; the treatment of the toxemia of pregnancy; cesarean section in placenta previa; contracted pelvis and the causes for the decrease in birth rate.

**Innocent Fibromyoma of Uterus.**—Dr. T. B. Eastman of Indianapolis presented statistics compiled from the literature, and referred to 169 cases operated on by him in which the degenerations found were as follows: Necrobiotic, 10; sarcomatous, 1; suppurative, 1; calcareous, 2; myxomatous, 3; adenocarcinoma of the body, 3; telangiectatic, 4; cystic, 7. He reported in full 5 cases illustrating the impracticability and impossibility of diagnosing certain conditions in these growths prior to their removal, and stated that it was advisable to remove all fibromatous tumors of the uterus in all cases, as is proven fully by statistics of cases operated on by competent operators and in cases not too long neglected. In his experience the menopause aggravates rather than improves the symptoms in at least half the cases.

Dr. Frank T. Andrews of Chicago said that he was absolutely opposed to the position taken by Dr. Eastman, because it was not only dangerous but vicious. He has seen many cases which were symptomatically cured by the menopause.

Dr. W. F. Wakefield of San Francisco said that he was absolutely in accord with Dr. Eastman.

Dr. J. H. Carstens of Detroit believed that more patients undergo a change for the worse if they are not operated on than will die if they are operated on. The time can be selected for the operation so that it will be free from danger. The mortality will then be so small that the stand taken by Dr. Eastman is a good one. It is the duty of the physician to relieve the mental condition of his patient, if she is suffering from a tumor, and that can be done only by early, careful, and efficient operation.

Dr. L. H. Dunning of Indianapolis did not think it correct to operate on every case of fibroid of the uterus. Many patients carry such tumors for fifteen or twenty years, sometimes without any knowledge of the existence of the tumor, and in such cases removal is not justifiable, especially when the patient is near the menopause.

Dr. D. H. Craig of Boston advised a neutral position, operating only on such cases as absolutely demanded operation.

Dr. C. L. Bonifield of Cincinnati directed attention to the fact that fibroids often complicate pregnancy, endangering the life of the patient; hence their removal was desirable.

**Cause of Failure After Successful Gynecological Operation.**—Dr. Wm. E. Ground of Superior, Wis., said that no matter how thorough the operation so far as technic is concerned, it cannot be other than a failure if it fails to afford the patient relief. As a rule, failure to cure was not so much the result of faulty technic as it was the result of failure on the part of the operator to consider thoroughly the individual case both before and after operation. Operation should not be performed for the relief of symptoms, but for the relief of the underlying condition or conditions that produce these symptoms.

Dr. J. H. Carstens of Detroit said that the great trouble why patients do not recover after operations was that the operator does not make a correct diagnosis. Because the patient was a woman the trouble was usually referred to her uterus and its appendages, without any regard for the fact that woman, like man, was subject to all kinds of diseases of the abdomen and its contents. Each case should be investigated thoroughly and a careful diagnosis made before operation is attempted. He cautioned the general practitioner against promising patients too much from operation.

*Second Day—Wednesday, July 12.*

**Tubal Pregnancy.**—Dr. J. Riddle Goffe of New York reported a case of extrauterine pregnancy illustrating the corroding function of the trophodermic cells of the chorion, which may extend through the entire wall of the tube and thus occasion most alarming hemorrhage, without rupture. After the birth of her second child, the patient had regular menstruation for about six months, when it ceased for one month, and then became very irregular and painful. Careful examination failed to reveal any evidence of pregnancy or disease of either the uterus or its appendages. Later there was detected a slight enlargement of one tube, which also was sensitive to touch. The tube was removed and a pinhole opening was found, but no chorionic villi. More careful examination showed that the ovum had eroded through the mucous membrane of the tube and was buried in the wall of the latter, thus explaining the cause of the hemorrhage, which had been a marked symptom in the case.

**Extrauterine Pregnancy.**—Dr. J. H. Carstens of Detroit reported two cases. The first patient, a III-para, had repeated attacks of pain, with temperature and evidences of pelvic inflammation. Examination disclosed a sac extensively adherent, containing a four and a half months' fetus. In the second case an existing swelling was diagnosed as abscess of the broad ligament. The pulse being 160, no extensive operation could be done. The abscess was opened immediately with scissors, the cavity was cleansed with sponges and a drainage tube was inserted. The patient recovered within two weeks. Previous to operation this patient had suffered with repeated attacks of very severe pain, irregular menstruation, and symptoms of pelvic inflammation. The author stated that extrauterine pregnancy ought always to suggest itself in cases of sudden onset of pelvic symptoms. Irregular menstruation is always suspicious. Inflammation and sepsis following a supposed miscarriage, are always due to rupture of a tubal pregnancy. Immediate operation is always indicated, whether by the abdominal or vaginal route depending on circumstances.

Dr. Gilmore of Chicago suggested as aids in making a diagnosis of tubal pregnancy the examination of the uterine scrapings for chorionic villi, and an examination of the blood for the purpose of determining whether the hemorrhage was the result of anemia or shock.

Dr. L. H. Dunning of Indianapolis called attention to the fact that extrauterine pregnancy at or near full term, without rupture, was exceedingly rare, and that in such cases a careful microscopic examination usually revealed a rupture.

Dr. C. O. Thienhaus of Milwaukee said that in cases like Dr. Goffe's immediate operation is indicated, even when a diagnosis of rupture cannot be made. Operation should only be deferred when the case has advanced to the seventh or eighth month. The most dangerous cases, he said, are those where rupture has occurred and nature has no time to form adhesions. It was inadvisable to transport such cases to the hospital. They should be operated on without any delay, and only in the exciting stage of ether anesthesia. When there is a tumor behind the uterus—either blood or pus—a simple vaginal celiotomy should be done. If there is blood, a diagnosis of extrauterine pregnancy may be made in 95 per cent. of the cases.

Dr. Perkins of Denver said that in many cases a woman will miss a menstrual period, imagine herself pregnant, and take some medicine to remove the product of conception. These agents contract the uterine muscle and prevent the impregnated ovum from passing into the uterus, thus producing an extrauterine pregnancy. In these cases the rupture of the tube usually occurs near the cornua.

Dr. D. C. Brockman of Ottumwa, Ia., reported a case of synchronous extra- and intrauterine pregnancy in which he attempted to do a panhysterectomy, but the extensive adhesions prevented the execution of such a procedure. A five months' fetus was removed from the tube through the vagina and the sac was packed. Premature labor followed, accompanied by severe hemorrhage, which persisted, and the patient died. He advised disposing of the fetus *in situ* by electricity or the injection of morphine and allowing the intrauterine pregnancy to go to term.

Dr. W. E. Ground of Superior, Wis., said that when the ovum is lodged near the uterus rupture occurs early, sometimes at the next menstrual period. He did not think that microscopic examination of the uterine scrapings is of any value as an aid in diagnosis because the chorionic villi are found in the tube only and not in the uterus.

Dr. W. O. Henry of Omaha said that when the ovum is lodged near the further end of the tube, the entire ovum with its coverings was extruded, but when lodged near the uterus rupture occurred with hemorrhage, the fetus being retained. He believed in conveying all patients to the hospital, unless the distance was too great.

Dr. C. L. Bonifield of Cincinnati reported a case of what appeared to be an unruptured tubal pregnancy at term. He did not think that was the case, however, but thought that rupture had occurred and that the organization of the blood clot had closed the opening. He advised that when the hemorrhage had apparently stopped and the patient was improving slightly to wait with the operation until the patient had recovered from the shock; but if the hemorrhage continued, and the pulse became more rapid, or could no longer be felt, then operate at once.

**Postoperative Pelvic Exudates.**—Dr. W. F. Wakefield of San Francisco advised the systematic study of all postoperative conditions in every case because postoperative exudates are found in about 60 per cent. of all patients operated on for the relief of conditions produced by severe inflammatory disturbance. These postoperative tumefactions are rarely observed while the patient is in bed, hence it was advisable to examine the patient carefully for several weeks or months afterward so that these exudates, if present, may be discovered and treated before the patient is finally discharged, thus ensuring better after-results. He thought that these tumefactions are probably the result of circulatory disturbances in the embryonic connective tissue in and around the site of the surgical trauma, intensified by the edematous hyperplastic condition of the pelvic connective tissue as a result of long-continued association with chronically inflamed viscera. As the pelvic circulation improved, a gradual absorption of this embryonic tissue took place and the tumefaction disappeared. If this did not occur, a hard fibrous mass was formed which might give rise to very distressing symptoms necessitating a secondary operation. A prolonged convalescence will often prevent this occurrence. Light general massage, alcohol and salt-friction rubs, tepid sponge baths, the depleting tampon and copious hot water douches, once or twice daily, are indicated. The tampon should consist of some light, fluffy, and non-absorbable material, such as Australian lamb's wool. The menstruum must be one which encourages free exosmosis. Incision and drainage through the vaginal vault he had never found necessary.

Dr. C. O. Thienhaus of Milwaukee said that the reason why postoperative exudates were not so frequently met with as formerly was because silk was not used any more in the abdomen.

Dr. D. H. Craig of Boston reported a case that had been examined by a number of physicians, each of whom succeeded in palpating a tumor in the region of the broad ligament. When examined at some other time, no tumor could be demonstrated, and then it would appear again. He suggested that this condition was caused by a varix in the broad ligament.

Dr. J. R. Goffe of New York advised early treatment of these cases, not waiting for the appearance of a tumefaction. If hot douches and the depleting tampon were used too early, however, the healing process will be delayed. He begins this treatment on the twelfth or fifteenth day, with good results. He believed that the tumefaction was plastic material thrown out by Nature, and thought it advisable to get at it before it developed into an abscess. It is important to follow up cases carefully after operative procedures in the pelvis, and patients should not be allowed to get up too early.

Dr. O. S. Bacon of Chicago said that this condition might be caused by hemorrhage, stasis, a varix, or a non-virulent infection. He believed that there is great danger in allowing patients to get around too early after operation, and in not getting them around in the proper way. The postoperative management of these cases should be like that of the puerperium, a proper period of rest in bed, followed by a carefully managed way of doing things.

Dr. J. H. Carstens of Detroit thought the number of these cases did not run as high as 60 per cent., and that they depended largely on the operator. The broad, general practitioner probably did not average over 4 or 5 per cent. If the operation was performed properly, exudates will not form. All stumps should be covered over carefully with peritoneum or with Cargile membrane, and dusted freely with aristol, which has a very beneficial effect in preventing the formation of adhesions and exudates. These patients should also receive plenty of water during their convalescence; water by mouth, salt solution per rectum, or, if not tolerated, injected under the breast. Plenty of water flushes the eliminating organs and hastens convalescence. At least three quarts of water should be given every day, one half pint or a pint at a time.

Dr. F. T. Andrews of Chicago advised amputating the entire tube even into the horn of the uterus, closing the wound with a whip stitch, running the stitch along the whole upper border of the broad ligament, if necessary.

Dr. J. H. Crowell of Kansas City, Mo., believed in permitting patients to get up as early as possible, even on the second day after operation, for the purpose of exercising all the muscles and thus facilitating drainage. He said that he permitted his patients to walk about on the second day after operation, even hysterectomy patients. He was satisfied that patients got along better than if kept too long in the recumbent posture.

**Hernia of the Fallopian Tube.**—Dr. F. T. Andrews of Chicago reviewed the literature and reported four cases. The first case was diagnosed as one of strangulated femoral hernia occurring in a woman aged 56. The hernial sac contained a portion of the ileum, which was very dark colored, a portion of the broad ligament, and a loop of the fallopian tube, with the ovary pressed firmly against the femoral ring and neck of the sac. The tube and ovary were replaced, the sac excised, and the wound closed with catgut. The patient made an uneventful recovery. In the second case, one of tubal hernia occurring in a woman aged 45, the cyst wall was connected with one of the fimbriæ of the tube. The end of the tube was amputated. The third patient, a woman aged 32, gave a history of gonorrhea. The operation disclosed that about one half of the tube was adherent, together with omentum, in the hernial sac. The appendages were removed, and the hernia repaired. The patient made a normal recovery. In the third case, a woman, aged 23, the abdominal wall on the right side was swollen and edematous, the swelling extending up to the ribs and down to the anterior surface of the thigh. The diagnosis was made of pelvic abscess due to rupture, with right pyosalpinx and adhesions. The pelvic organs on the right side were matted together and covered by adherent omentum and intestines. The right tube and round ligament had been severed at the uterine horn. Free drainage was instituted, and the patient made an uneventful recovery.

**Gonorrhea in the Female.**—Dr. L. H. Dunning of Indianapolis considered the question of gonorrhea in the adult female as it affects her reproductive organs only. Acute

gonorrhea is easily diagnosed, if seen early, when both the smear and culture methods may be employed. In the chronic and subacute cases a positive diagnosis is often impossible. All secondary aids to diagnosis, such as the confession of the patient, sudden onset of inflammatory lesions without other cause, must be employed. Many cases in women recover quickly, leaving behind no trace of the disease, and communities differ with respect to the prevalence of the disease. The author does not believe that gonorrhea is responsible for pelvic lesions in women as often as is generally believed. Of a series of 1,855 cases coming to his notice and being under his care, 88 had gonorrhea as was demonstrated microscopically. Of 199 cases of serious lesions of the pelvis demanding grave operative procedures, only 35 were of gonorrheal origin. As to the influence of gonorrhea in producing sterility, out of 59 cases of primary sterility, 66 per cent. could be fairly attributed to other than gonorrheal causes and only 10 per cent. could be attributed to gonorrhea, indicating that gonorrhea as a causative factor in sterility has been overestimated. Dunning believes that sterility is frequently due to a successful effort on the part of the woman to prevent impregnation, and to errors in development of the reproductive organs of woman.

**New Operation for Pyosaplinx.**—Dr. W. D. Kelly of St. Paul, Minn., described a method employed by him which does not necessitate the use of either clamp or ligature, and which is not accompanied by any bleeding. The mortality of the operation is under 2 per cent. Drainage is almost never necessary and counter openings are unnecessary. He said that extratubal or peritubal abscess is frequently found whose walls are made up of bowel, omentum, tube, broad ligament, uterus, or bands of adhesions. This condition is frequently mistaken for ruptured abscessed ovary or tube, it being impossible to separate or encroach on this abscess without opening it. He did not hesitate to operate on an acute case of pyosalpinx if the tube can be felt free in the pelvis. Fifty-nine cases were cited.

**Bi-inguinal Operation for Retroversion of Uterus.**—Since 1903 Dr. A. Goldspohn of Chicago has operated on 55 cases, employing this method. Five of these cases have disappeared. One case died suddenly with symptoms of cerebral embolism. Forty-nine cases were examined on an average twenty-two months after operation. In five the uterus was adherent; in nine the appendages of both sides; in five the appendages on one side; cystic follicles, corpora lutea and cirrhotic portions of the ovary were incised from the right 26 times, from the left side 31 times. Salpingostomy, 2; parovarian cysts, 2. Primary union occurred in all except five cases. Collateral operations done at the same time were: Curettage, 49; amputation of cervix, 7; Emmett operation, 1. A number of these cases have stood the test of labor without a recurrence of the retroversion. Out of 170 cases operated on by his method only three were failures, and those for special reasons mostly.

**Normal Anatomy in Gynecological Surgery.**—Dr. D. H. Craig of Boston believed that there are many perfectly satisfactory operations anatomically, symptomatically, and functionally. Quotations made from letters received from a number of prominent operators who have devised special operations for the treatment of retroverted uterus show that none of the methods is suitable in all cases. Craig believed that the greater the number of ways devised for utilizing the normal uterine ligament for the restoration and retention of the uterus in its normal position the better, as long as they are rational and safe and are considered as supplements instead of substitutes for each other. Every surgeon, whether specialist or general practitioner, intending to operate on such cases should familiarize himself with all known methods and be prepared to use any and all methods or to modify them to meet the conditions of each individual case. The skill and time required are not excessive. The formation and utilization of adventitious ligaments within the abdomen should be reserved for cases manifesting special indications. Ventral suspension or fixation should not be performed, because of their easy performance, by surgeons who could not operate by using the natural ligaments. The conservation or restoration of normal pelvic anatomy should be the aim of the gynecologist, and the individual case should determine the method to be employed.

Dr. W. O. Henry of Omaha has devised an operation which extends the vesicouterine ligaments on the anterior surface of the uterus without dissecting the bladder free from the uterus. The peritoneum in the cul-de-sac is scarified between the uterus and bladder, extending the scarification up on the uterus in the course of the ligament as far as may be necessary, depending on the size of the body of the uterus.

Dr. Gallant of New York puts a needle threaded with catgut around the middle of the round ligament, attaching it to the peritoneal surface on the other side. Two sutures are employed, about half an inch apart.

Dr. Frisbee of San Francisco detaches the round ligament at its junction with the uterus, passing a pair of forceps beneath the broad ligament through the ovarian ligament and tube, seizes the detached ligament and brings it around back of the uterus and stitches the end of the one-round ligament to the other, first making a slight furrow in the back of the uterus. Stitch over all of the ligaments peritoneum. It leaves no place for the formation of adhesions and tilts the uterus forward.

**Etiology and Treatment of So-called Endometritis.**—Dr. E. F. Tucker of Portland said that endometritis of the body of the uterus is not a true mucous membrane, but a glandular structure intimately connected with the muscular tissue of the uterus. Its main function is connected with the development of the fertilized ovum. Both acute and chronic endometritis he considered as being rare affections. Fungoid endometritis is not a condition at all, and the term ought to be expunged from the records. The condition which usually is termed endometritis is the result of circulatory disturbances in the pelvic organs. The treatmen consists of the removal of the cause. Local measures are of no avail. He advocated a careful study of this condition with a view of determining definitely its pathology, and also urged that gynecologists perfect their knowledge of the anatomy, physiology and pathology of all the organs in the pelvis and abdomen.

*Third Day—Thursday, July 13.*

**Repair of Perineum.**—Dr. G. B. Somers of San Francisco described the anatomy of the perineum and insisted on the importance of the levator ani muscle in attempting a restoration of this body. He described an operation called the fishing operation, for exposing and uniting the fibers of the levator ani. A simple denudation was made and the levator muscle feed from its surrounding tissues. The ends were united directly, using silkworm gut. The suture was inserted with a matress stitch, from side to side, in the deepest portion of the wound, passing through the edges of the muscle two or three times. He then continued in the deep portion of the wound, taking up the tissue from the denuded ends of the superficial perineal muscles, emerging, finally, through the skin on the perineal surface just above the lower angle of the wound. A second and third stitch were taken in the same way, approximating the tissues. The most important feature of the suture was the method of fastening the ends. After making certain that all the sutures are drawn taut, the vaginal ends are gathered into a single shot and clamped from an inch to half an inch from the free surface. The perineal ends were likewise clamped. The sutures keep the parts in perfect contact and also allow for swelling. There is no pain at any time. The sutures were removed on the tenth day. There is no constriction of circulation, thus favoring immediate union.

Dr. J. H. Carstens of Detroit did not agree with the author, either in his anatomy, physiology, or technic. He said that the levator muscle is not the support of the perineum. It was the fascia. Furthermore, there is no

one correct way for repairing the perineum. The individual case must be considered, and that operation performed which was most suitable. He thought that Dr. Somers' stitch would tear through the tissues, and thus fail of accomplishing its object. He advised putting in many little sutures rather than one large suture, using catgut and not silkworm gut.

Dr. H. O. Marcy of Boston agreed with Dr. Carstens, and referred briefly to his method of repairing the torn perineum.

Dr. W. F. Wakefield of San Francisco said he had employed Dr. Somers' method in a number of cases, and had always found it perfectly satisfactory.

Dr. Ferguson of Troy, N. Y., insisted on the equal importance of both muscle and fascia, a repair of either alone not sufficing for a perfect restoration.

Dr. Clark of San Francisco had employed the method in fifty cases with most satisfactory result. He had never had a single case of infection. If infection had occurred before operation, the method was a most valuable one for treating the infection. In fresh tears, particularly, the suture advised was of great value.

Dr. C. S. Bacon of Chicago said that while the levator ani muscle was important, the muscle of the urogenital trigone must not be overlooked, because it supports that part of the pelvic outlet which is not supported by the levator ani. He thought that Dr. Somers' method failed to bring together these muscles.

Dr. F. B. Andrews of Chicago called attention to the fact that the levator ani muscle was a shallow bowl and that unless this shape was restored to the muscle, the operation employed was useless. The stitches should be inserted so as to draw all the tissues upward and forward, thus bringing the pelvic outlets back to their normal position and giving to the vaginal canal its normal obliquity. Most operations did not do this; they created a vaginal canal whose direction was horizontal and not oblique.

**Complications of Pregnancy.**—Dr. F. D. Donoghue of Boston said that where there was a well-marked history of appendicitis in a young woman, operation should be performed as an antecedent to marriage. With well-marked acute symptoms referable to the right side, in the presence of pregnancy, operate at once. Operation should be advised prior to marriage if tumors of the uterus or appendages are known to be present. The treatment of ovarian or uterine tumors not recognized until pregnancy had occurred, should be governed by the conditions existing in the individual case. At or near term an operation may be performed which will remove the condition, and at the same time permit of the delivery of a living child.

Dr. E. E. Montgomery of Philadelphia said that if the patient had had repeated attacks of salpingitis, it was an indication for immediate operation in the early stage of pregnancy. The danger of operating at this time was less than it was later on in the pregnancy. In cases of myoma, unless the tumor interferes greatly with the circulation, it is better to wait and see whether Nature may not lift the tumor out of the way so that it will not interfere with the pregnancy. Besides, the tumor may disappear entirely after the pregnancy. Ovarian tumors should not be interfered with unless they are situated below the uterus. Then operation should be done as early as possible.

Dr. C. S. Bacon of Chicago said that all ovarian tumors should be removed as soon as discovered, except in exceptional cases. During labor it is not safe to operate on these cases. Large tumors that fill the pelvis can often be replaced by putting the patient in the knee-chest or Trendelenburg position. Reposition is better than operation. He did not believe in operating on fibroids even in the early months of the pregnancy, because they rarely become troublesome during labor, and if the fibroid is not situated in the cervix or lower uterine segment, it is better to let it alone.

Dr. J. H. Carstens of Detroit said that a woman will stand an operation as well during pregnancy as at any other time. Adherent ovarian tumors should be removed as soon as possible, because they cannot be gotten out of the way. Fibroids in the cervix or lower uterine segment can be removed through the vagina in many cases. Many more women die with tumor during pregnancy and labor than is the case when they are operated on promptly. If the tumor is loose and movable, above the brim of the pelvis or subperitoneally, it should be left alone.

Dr. W. B. Dorsett of St. Louis agreed with Dr. Carstens, but urged conservatism in cases of fibroids complicating pregnancy.

**Pulmonary Tuberculosis as an Obstetrical Complication.**—Dr. C. S. Bacon of Chicago said that probably from one to one and a half per cent. of all pregnant women had tuberculosis in such a degree that it could be detected if careful examination was made. In many cases the pregnancy had a bad effect on the disease, especially when it had progressed far or nutrition was low and the respiratory function is much embarrassed. Labor was very apt to have an unfavorable influence on the disease, and not rarely led to a fatal termination. The puerperium was characterized by a rapid progress of the affection. The effect of tuberculosis on pregnancy was slight, except in severe cases when there was much coughing and fever. Only rarely was the fetus infected. In mild forms of the disease labor might be normal. Generally, it was the puerperium that showed most markedly the effect of tuberculosis, and when the exhaustion of labor was considerable, the patient was apt to die. In the case of a woman living under favorable conditions, conception should be absolutely forbidden. For these women artificial sterilization was a legitimate operation. The tuberculous gravida should be permitted to continue her pregnancy if she could receive proper care; if not, an operation should be advised before the twentieth week. After that time an attempt should be made to carry the child to full term. Under no circumstances should the tuberculous mother nurse her child, and it should not be kept in the same room with the mother. By careful arrangement of a case before and after labor, and the free use of oxygen during labor, complications usually did not arise.

Dr. E. F. Tucker of Portland said that in the production of an abortion we must be guided by the location and stage of the tuberculous process, the stage of the pregnancy and the social condition of the mother.

Dr. E. V. Davis of Chicago said that abortion was not justified. It was better to save the life of the child than that of the mother, who probably had not much longer to live anyway. It was better to teach the dictum never to perform abortion, than to say that it may be performed under certain conditions.

Dr. W. O. Henry of Omaha protested against performing abortion in these cases.

Dr. J. H. Carstens of Detroit advised educating the laity in these matters, and would forbid the marriage of consumptives. He did not agree with Dr. Bacon that sterilization ever was justifiable, because the mother might be cured of her tuberculosis and then want a child, when that would be no longer possible.

Dr. F. D. Donoghue of Boston agreed with the previous speaker, and said, further, that to induce an abortion in these cases was an acknowledgment that physicians were unable to cope with tuberculosis, which was not true.

**Maternal Syphilis.**—Dr. G. S. Whiteside of Portland advised looking oftener for syphilis, as it would often explain otherwise obscure symptoms. If it was detected in a pregnant woman, it should be treated promptly and thoroughly, because only in that way was it possible to save the fetus from inheriting the disease. The syphilitic infant should be given every care and mercury. After thorough treatment immediately after birth, the late symptoms of hereditary syphilis were seen but rarely.

**Physiological and Legal Status of the Fetus in Utero.**—Dr. W. H. Sanders of Montgomery, Ala., said that if birth meant the coming into life, birth took place at the time of conception. Delivery meant simply the passing from intrauterine to extrauterine life. The conjunction of the male and female sperms constituted birth, and physicians in dealing with pregnancy, from the earliest to the latest stages, should realize the extreme gravity of the question, and should never attempt to destroy a fetus, however young, without mature consideration and without calling to their aid the highest professional authority. He urged that these principles should be impressed on the medical profession, taught to medical students, and promulgated among the laity. Medical men should see that the statutes of their respective States are ample for the protection of the fetus in utero.

**Present-Day Conduct of Labor Cases.**—Dr. J. A. McKenna of Lansdowne, Pa., gave a brief analysis of 207 cases of labor without hemorrhage, sepsis, or fatality. Forceps were used only twice, in a case of right occipito anterior position and in a primipara of thirty with uterine inertia. Among this number there were three cases complicated by uterine fibroid. The technic pursued was that laid in most textbooks on the subject, except that the position of the patient in bed differed from that usually assumed. The hips of the patient were elevated as much as possible, thus obviating the danger of sepsis from the entrance into the vagina of septic material or material which may decompose and thus cause a sapremia. In gonorrheal cases, the author dilated the vagina for weeks before delivery, and swabbed its walls with a solution of albuminate of silver. He was utterly opposed to the use of douche at any time during or after delivery, and advised noninterference as regards retained placenta. Thorough compression of the fundus of the uterus during labor facilitated the expulsion of the placenta.

**Study of Bony Pelvis.**—Dr. E. V. Davis of Chicago made a systematic study of 150 cases of pregnant women, especially with reference to the bony pelvis. About 82 per cent. of the cases were normal; 69 per cent. of the deformities were contracted pelves, about 15 per cent. simple flat, and 4 per cent. rachitic. In the deformed cases, about 61 per cent. had normal deliveries; 38 per cent. were operative cases. Cesarean section was performed only once. Of the normal cases, 124 were delivered spontaneously and 12 were operative cases. A study of 35 cases made with a view to determining whether the occupation, diet, and social status of the mother had anything to do with the weight of the child, showed that the more inactive the mother, and the better she was fed, the greater the weight of the baby. Of American mothers, 19 per cent. had deformed pelves, and 33.01 per cent. of the foreign women. The author stated that deformed pelvis should be looked on as a sign of degeneracy. These deformities occurred often enough to make pelvimetry a routine practice in all cases of pregnancy. Inebrity in parents was the most prominent factor in causing these deformities. The size of the infant can be regulated by diet and exercise, if these measures were carried out during the last three months of the pregnancy, a point well worth remembering in these cases of contracted pelves.

**Maternal Impression Superstition in Obstetric Teaching.**—Dr. E. T. Shelly of Atchison, Kan., reviewed this question, and stated that all anatomical and physiological facts were against the possibility of there being any truth in the theories advanced in favor of maternal impressions. He advised that teachers of obstetrics and physicians generally do all in their power to eradicate this belief from the minds of the laity, because of its depressing effect on the pregnant mother.

**Syncytioma Malignum.**—Dr. L. H. Bransom of Iowa City reviewed the clinical history of this condition, and reported one case illustrating the fact that this form of tumor may coexist with pregnancy.

## AMERICAN NEUROLOGICAL ASSOCIATION.

*Thirty-first Annual Meeting, Held in Philadelphia June 1, 2, and 3, 1905.*

(Special Report to the Medical Record.)

(*Continued from page 81.*)

The President, Dr. William G. Spiller, in the Chair.

**The Mental Symptoms of Cerebral Tumor.**—Dr. Phillip Coombs Knapp of Boston presented this paper. The writer had made a study of the mental symptoms in 104 cases of tumor of the brain with autopsy observed at the Boston City Hospital. Mental disturbances were noted in 79 cases; 40 cases, however, were excluded on account of complicating diseases and for other reasons. In the remaining 64 cases mental symptoms were noted 58 times, and the writer believed that such disturbances were far more frequent than had been previously stated. The mental symptoms were observed early in the progress of the disease in 28 cases. The nature of the mental disturbances varied. The largest number of patients, 31 in all, showed simple mental failure and dullness; 7 showed a marked mental confusion and 15 actual delirium; 1 patient was simply neurasthenic, 2 had delusions of persecution, 1 was depressed, another showed symptoms of general paralysis. The especial *Witzelsucht* so often described was not observed. The states of delirium were not apt to be noted in the larger stages of the disease. The writer found that a tumor on the left side of the brain was not more apt to produce mental symptoms than a tumor on the right. In regard to the location of the growth, in the only case of a tumor of the cerebrum in which mental symptoms were not noted, the tumor was in the frontal lobe. The writer, however, believed that the frontal and temporal lobes were more especially to be regarded as presiding over the higher psychical functions. The mental symptoms seemed less probably the result of a lesion in a definite portion of the brain than the result of general processes such as pressure and the formation of toxins. The nature of the mental disturbances suggested a toxic origin, and in 1 case they developed after an attempt at removal of the tumor had relieved the increased intracranial pressure.

Dr. Hugh T. Patrick of Chicago said there was one element in connection with the mental symptoms of brain tumor that the author did not allude to, viz., the individual tendency of the patient before the tumor had begun to develop. In some cases he had been able to determine the character of this tendency. He had found the *Witzelsucht* in 2 cases; 1 was thought to be frontal tumor and the other just behind the central region. No autopsies could be obtained.

Dr. Guy Hinsdale of Philadelphia said that he had seen *Witzelsucht* in a boy 18 years of age in whom a large frontal growth was removed at operation. The boy was constantly in a state of extreme exhilaration.

Dr. Knapp in closing said that he did not consider in his paper the previous mental tendency of the individual, as nearly every one of his cases presented distinct mental symptoms.

**Carcinoma of the Nervous System.**—Drs. Wm. G. Spiller and T. H. Weisenburg of Philadelphia presented this communication, which was read by Dr. Weisenburg. They called attention to the lack of information upon this subject and made a classification, basing this upon the study of the literature and of their 8 cases, 6 of which were with necropsy. The following subdivisions were made: (1) Those cases in which metastasis to the nervous system occurred; (2) those in which there were alterations not distinctly cancerous, in the substance of the spinal cord and brain; (3) those in which the peripheral nerves were diseased either with or without involvement of the brain and cord, and (4) those in which no macroscopic lesions were found, and the symptoms were supposedly toxic. Metastasis to the brain might be in the form of cancer nodules or might be a carcinomatous meningitis. Metastasis to the spinal cord was

rare, but vertebral metastasis was more common. The alterations in the nervous system might be in the form of diffuse sclerosis, and more rarely involve definite tracts. The toxic symptoms were various, and no microscopic lesions could be found to explain them. It was not unusual to find alterations in the nerve cells in different parts of the brain and cord. Of the 8 cases studied by Drs. Spiller and Weisenburg, one was a case of carcinoma of the optic chiasm, one case of degeneration of cranial nerves, one a case of carcinoma intoxication after operation, one a case with bulbar symptoms, and four were cases of vertebral carcinoma.

Dr. E. W. Taylor of Boston stated that he was very much interested in the paper of Drs. Spiller and Weisenburg, especially in reference to the part dealing with classification. He had had two cases of carcinoma of the nervous system. One was carcinomatous meningitis secondary to cancer of the breast. The symptom complex was that of pachymeningitis. There were distinct nerve root symptoms. The other case was in a woman with cancer of the breast. He made an autopsy half an hour after death. Though he at first thought the mental symptoms were of a toxic variety, he found later by careful study with the Nissl method retrograde axon degeneration. He exhibited a photomicrograph showing the changes in this case. Taylor considered photomicrographs better than other forms of reproduction for showing changes in the nervous system.

**Palates of the Feeble-Minded.**—Drs. Walter Channing of Brookline, Mass., and Clark Wissler of New York, presented this communication, which was read by Dr. Channing. They reported upon the measurements of the palates of feeble-minded and normal individuals which they had been making for a number of years past. All of the work has been done with plaster casts of the palate. They had casts of the palates of 1,010 feeble-minded persons and 614 normal individuals. By comparing the two classes very little difference was found, and this difference was principally in respect to variability.

**Paraplegia from Fracture of the First, Second, and Third Dorsal Vertebræ.**—Dr. Guy Hinsdale of Philadelphia presented this paper. The patient, a young lady, was injured in 1901 by the explosion of an acetylene gas generator. She suffered fracture of the first, second, and third dorsal vertebræ and seven other fractures, including a comminuted fracture of one elbow and a compound fracture of one ankle. There was a paraplegia below a line two inches below the nipple. There was no deformity of the vertebræ and no crepitus but great tenderness. Upon consultation laminectomy was decided upon and performed. The dura was incised for about an inch. The operation was followed by convulsive movements of the parts not paralyzed. Convalescence was very long and tedious, requiring infinite care and patience. There was no loss of consciousness at any time as a result of the accident. Bed sores developed. Although it required three years for restoration of the functions of the bladder and rectum, and catherization was performed during all this time, cystitis did not occur. A glass catheter was used and always by the same nurse. Spastic paraplegia came on accompanied by contractures requiring division of the Achilles tendons, adductors of the thigh, and the hamstrings. Dissociation movements were very prominent and resembled those of syringomyelia. The patient could now sit up, stand alone, take long drives, walk by the aid of two nurses, and was fairly comfortable and happy.

**A Case of Brown-Sequard Paralysis, Due to a Fall Upon the Head; Operation; Autopsy.**—Dr. William C. Krauss of Buffalo read this paper. The patient was a colored boy who fell from a hayloft a distance of twenty feet, striking on his head. He was unconscious when brought to the hospital, where the resident staff thought the case was one of hysteria. Several days later, on examination, Krauss found the seat of injury at the fourth cervical segment, loss of sensation of the right arm and leg, and loss of power of the left arm and leg. Laminectomy was performed, and, although softening of the cord was noted, no foreign body was seen. No fracture or dislocation of the bodies was present. About a week later the patient died, apparently as the result of infection, and autopsy revealed a small spicule of bone which had penetrated and injured the right side of the cord. It was not found at operation because the search was confined to the opposite side. There was adhesion of the meninges, with degeneration in the tract of Goll and of Gowers. Injury in this region was dangerous because of involvement of the phrenic and the long thoracic nerve. The author was able to find reports of about sixty cases of Brown-Sequard paralysis.

**Hyperesthesia and Hypalgesia and Their Significance in Functional Nervous Disturbances.**—Dr. Edward B. Angell of Rochester presented this communication. He spoke of the importance of the skin as a sensory organ of the nervous system and called attention to the common origin, in the ovum, of the skin and the central nervous system. In peripheral anesthesia the muscular and pain sense were lost before the tactile sense, while in central anesthesia the reverse was true. A fixed idea might blunt the surface sensibility. Also the surface sensibility might be blunted without the patient being aware of it. He cited the case of a woman who had nursed a patient with diphtheria under a doctor who was very careful about disinfection and required her to wash her hands frequently. As a result of the mental influence her hands became anesthetic. He called attention to the recent discovery of Head of two sets of cutaneous nerves, one for pain and one for touch.

Dr. P. C. Knapp said he thought the anesthesia of the hands in the case of a woman referred to by Dr. Angell was due to the action of soap and water used in the frequent washing in a manner analogous to that in which washerwomen are sometimes affected.

**Officers Elected.**—*President,* Henry L. Stedman of Boston; *First Vice-President,* Henry M. Thomas of Baltimore; *Second Vice-President,* George W. Jacoby of New York; *Secretary* and *Treasurer,* Graeme M. Hammond of New York; *Councillors,* Wm. G. Spiller of Philadelphia, Walter Channing of Boston.

---

## Philadelphia County Medical Society.

At a stated meeting held May 10, Dr. S. C. Burns presented for Dr. W. L. Rodman "A Case of Gastrostomy" occurring in a man about 50 years old, with obstruction at the cardiac extremity of the stomach, with ability to swallow only small amounts of fluid. The patient was greatly emaciated and debilitated, and a fistulous opening was made into the stomach through an incision close to and parallel with the left costal margin after the viscus had been attached to the parietal peritoneum and included within the margins of the divided rectus muscle. In this way a sphincteric action was obtained, preventing the leakage of gastric juices and excoriation of the cutaneous surface surrounding the fistula. The patient gained in weight and strength after the operation. Dr. H. Emerson Wetherill presented a centrifugal apparatus operated on the principle of the whirligig. The device was simple and portable and the cubes were graduated so that the amount of precipitate could be read from a scale etched on the glass. Dr. M. H. Fussell read a paper entitled "Two Cases of Malignant Endocarditis." One occurred in a lad with a history of previous typhoid fever and later presenting symptoms suggestive of appendicitis. There was severe pain in the right iliac fossa, with distinct leucocytosis and a somewhat hectic temperature. In addition, murmurs were audible at the aortic orifice, and on this account operative intervention was refrained from. Death resulted and examination disclosed the presence of ulcerative endocarditis involving the aortic valves. In the second case also there was a history of typhoid fever, but typhoid bacilli were not agglutinated and rendered immobile by the blood-serum. On account of the size of the heart and especially the enlargement of the right side of the viscus, the presence of leucocytosis, of enlargement of the spleen and of a presytolic murmur at the

mitral orifice a diagnosis of malignant endocarditis was made. After death the mitral valve was found the seat of large vegetations and the spleen contained several infarcts. Dr. Fussell dwelt especially on the resemblance of the first case to one of appendicitis and the history of typhoid fever in both cases, the apparent symptoms of the latter being merely due to the endocarditis. Dr. NORMAN B. GWYN read a paper entitled "Typhoid Fever; Accidental Infection with the Bacillus of Malignant Edema or the Gas-bacillus, with the Symptoms of Intrathoracic Irritation." Hypodermoclysis was employed in the course of treatment and was followed by the development of subcutaneous emphysema in the vicinity of the needle puncture is one situation. Large bacilli suggestive of hay-bacilli were isolated from the fluid present. Dr. G. BETTON MASSEY read a paper entitled "Some Aspects of the Cancer Problem," in which he dwelt upon the primarily local origin of the disease and the need of early recognition and prompt removal by the cautery, by cataphoresis, or by the knife. Patients thus treated must subsequently be kept under frequent observation for a long period of time, in order to guard against recurrence.

## Medical Items.

**Contagious Diseases—Weekly Statement.**— Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending July 15, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 458 | 17 |
| Diphtheria and Croup | 187 | 27 |
| Scarlet Fever | 50 | 5 |
| Smallpox | ..... | ..... |
| Chickenpox | 34 | ..... |
| Tuberculosis | 371 | 136 |
| Typhoid Fever | 94 | 12 |
| Cerebrospinal Meningitis | 34 | 32 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1,228 | 229 |

**A New Form of Needle.**—Loopuyt describes a new pattern of surgical needle which is intended to be used by the fingers without the aid of a holder. Especially in intestinal work it is of advantage to be able to dispense with the holder, but with the ordinary straight needles it is often difficult to penetrate the desired layers accurately or to work at any distance from the surface. The new needle has a straight shaft with a gently curved point. The eye end for a distance of 1.5 to 2 cm., according to the size of the needle, is bent quite sharply at right angles to the shaft, the plane of curvature being the same as that of the point. By grasping the needle at the eye and with the ball of the thumb in the hollow of the curve, perfect control is secured, while the curved point affords all the advantages of the ordinary curved needle. —*Zentralblatt f. Chirurgie.*

**Suture of the Bladder.**—Hofmann attaches great importance to careful preliminary treatment of the bladder before suprapubic cystotomy in order to facilitate healing of the incision by relieving the inflamed or irritated state of the mucous membrane usually present in cases requiring operation. Rest in bed for some time and the internal administration of antiseptics and the application of moist compresses to the abdomen, bladder irrigations, etc., are the measures to be employed. Two other features of the author's technique are the omission of drainage from the wound, and of the permanent catheter. He does not consider the presence of either of these necessary for healing, and thinks that their absence tends to favor union of the incision.—*Zentralblatt für Chirurgie.*

**Tic-Douloureux from Sphenoidal Disease.**—John O. Roe reports this interesting case: The patient, a woman sixty-eight years old, was referred to him on account of a severe facial neuralgia, or tic-douloureux, from which she had been suffering for about two years. At first the pain was slight, but it steadily increased both in frequency and in the intensity of the paroxysms. When she was twelve years old she had fractured her nose, and in consequence of this accident there was for three or four years a thin mucopurulent discharge from the left lacrymal duct. This subsided spontaneously. She then became subject to severe colds in the head. During these attacks she had severe pain above the nose and behind the eyes. Finally the tic-douloureux began. Examination showed the right middle turbinate to be much enlarged, and pressing against the septum, which was deflected to the left, occluding the left nostril. The writer removed a portion of the right middle turbinate and the impaction in the region of the posterior ethmoid cells. Relief was obtained for one week, after which the paroxysms of pain were as frequent and severe as before. On exploring the posterior part of the nasal chamber pus was observed coming from the sphenoidal sinus. In using the probe there was a sensation of a doughy substance, evidently a growth in the cavity. Another operation was performed. The sinus was freely opened, the lower anterior wall was removed, and the interior of the cavity, which was filled with a myxomatous growth, was curetted. After the removal of this growth the paroxysms of pain ceased and have not returned up to the present date. The writer describes another case of this nature occurring in a woman seventy years of age. Operation was successful.—*Medical Review of Reviews.*

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended July 15, 1905:

### CLINICAL SUGGESTIONS FROM THE STUDY OF 500 CASES OF PULMONARY TUBERCULOSIS.*

By HENRY P. LOOMIS, M.D.,

NEW YORK.

The cases of pulmonary tuberculosis which have formed the basis of certain conclusions to which I ask your attention, represent people seen in private practice in New York; cases admitted to the big public hospitals of the city—the New York and Bellevue hospitals—and patients in the sanatorium at Liberty, N. Y. They include people taken from every walk in life and illustrate the disease in all its phases. They may be called in a certain sense selected cases, but selected from among a large number only because the records were so complete as to be of value and to warrant analysis.

I will ask your attention briefly to four series of investigation.

1. How pumonary tuberculosis begins—the symptoms of its very first inception—analysis of 100 cases.

2. Analysis of 55 "cured cases" of phthisis.

3. Results in cases examined for admission to the Adirondack Cottage Sanatorium, or the Annex of the Liberty Sanatorium, as illustrating the possibilities of prognosis.

4. Cases showing the average length of life of the poor after the inception of tuberculosis—patients living under such hygienic conditions as are possible for them in a great city.

**How Pulmonary Tuberculosis Begins.**—There is no disease in which an accurate history, especially as to the very beginning of the trouble, is of more importance than in tuberculosis. No detail is too small to be noted, and we quickly recognize that the statements of patients as to the beginning of trouble in most cases refer to later symptoms of the disease. With this fact in mind I am in the habit of keeping histories of the early symptoms of the disease under two heads: (1) First presumable evidence of the disease; (2) First demonstrable evidence of the disease. Naturally the filling out of this last heading must be based upon the physical examination of the chest, or the sputum examination, or both. To see if there was any uniformity in the histories of tuberculous people, as to the very beginning of their trouble, or to see if they could be classified under certain heads, I took a hundred cases in which the most accurate and painstaking histories had been obtained, as to how the trouble began, and I endeavored to analyze them. In 80 per cent. of all the cases the first *presumable evidence* of the disease was such that the cases could be arranged under one of three heads, viz.: (1) Colds or coughs (continuing); (2) "Run down," loss of weight, no cough at first; (3) Pleurisy, dry or with effusion.

In analyzing these groups further, I found as one might expect, that in the great majority of cases 48 per cent. of the whole, the first symptom of any pulmonary trouble was a cough, which ran for weeks or months and did not clear up, the cough antedating any "run down" condition, fever or chest pains. An interesting fact was that in 20 of the cases the cough was accompanied by no expectoration.

In 18 the first presumable evidence of the disease was loss of flesh, associated with a general "run down" condition. The person being "below par" physically for a varying period.

The average time this condition lasted before the actual development of the disease was found to be five and one-half months. In some of the cases, persistent digestive disturbances marked this period of loss of flesh. The following cases illustrate this point:

Case No. 1167.—First presumable evidence of disease. In 1896, when patient was 19 years of age, he entered upon a university course at Harvard. Went in enthusiastically for football and rowing, and was evidently overtrained during his freshman year, losing considerable weight. Appetite and digestion failed and he was treated for "stomach trouble." During the summer vacation he recovered weight and general health. The following three years of his university life were not marked by sickness, although he always complained of digestive disturbances and remembers having more or less cough at such times. After graduation, in 1900, he spent a year in manufacturing business. In 1901 he entered a banking house. Within a few months, however, he noticed recurrence of the cough, which was now attended with expectoration, but as general health and weight were not affected he paid no attention to the symptoms. In July, 1904, an unusual exertion (rowing in a scull race) was followed by a severe chill, although he saw no physician and continued his exercise. In September he noticed chill and fever, the latter reaching 102°F., and finally toward the last of the month the patient consulted a physician, who diagnosed tuberculosis. First demonstrable evidence of disease—physical examination in September, 1904, revealed a lesion, and on examining the sputum, bacilli were found.

Fourteen of the patients who developed tuberculosis gave a definite history of having had at some time one or more attacks of pleurisy, from which they recovered, and which were followed by periods of perfect health. Out of another series of 260 cases of pulmonary tuberculosis I found that 44 gave a definite history of having had an attack of pleurisy some time in their life previous to the development of tuberculosis. Taking the two series of cases together, this would give 16 per cent. as the average of tubercular cases who give a pleuritic history. The average length of time which was found to have elapsed between the first attack of pleurisy and the actual development of the disease was three and

*Read at the first annual meeting of the National Association for the Study and Prevention of Tuberculosis, 1905.

one-half years. As far as could be ascertained tuberculosis developed in these cases on the side that had been affected by the pleurisy. To ascertain if possible what proportion of cases had had an attack of pleurisy with effusion, and had not developed tuberculosis within five years, I had the records of Bellevue Hospital looked up. Picking out 50 cases with definite histories on this point, I found that 38 had not developed tuberculosis, and 12 had developed tuberculosis. The period of five years was taken arbitrarily to bring the two classes of cases together.

Taking out 80 per cent. of the cases in which the very first evidence of the disease came under one of these three heads, "Cold and coughs," "run down," or "pleurisy," the 20 per cent. left was about evenly distributed between attack of grippe, chills and fever (malaria), pneumonia (prolonged recovery), enlarged cervical glands, hemoptysis.

Only four cases in the hundred gave a history of hemoptysis in a person apparently in perfect health, and with not the least symptom of any underlying condition, such as a cough or loss of flesh, and most of these hemorrhages were slight and were followed by periods of good health before the actual development of the disease.

I believe first that when hemoptysis occurs it represents in the vast majority of cases a demonstrable evidence of tuberculosis, and second, that even if no positive evidence of a local lesion can be demonstrated, and the hemoptysis is slight and quickly recovered from, and the cases are watched long enough, active tuberculosis will always develop. It is, in my opinion, the one symptom that never fails in patients under 30, granting that they have no cardiac lesion, cirrhosis of the liver, or are not "bleeders."

In 24 of these 100 cases the actual development of the disease, the demonstrable evidence, I mean, was ushered in by hemoptysis. The spitting of a little blood, no matter how slight, even when it does not last and is followed by no constitutional disturbances, should be looked upon really as the actual development of tuberculosis and not as indicating, as many believe, only a tuberculous tendency. Another interesting point in the study of these 100 cases is in the consideration of the very earliest evidences of the beginning of the disease and what these evidences were.

The first demonstrable evidence, apart from the history, was an examination of the lungs and the presence of tubercle bacilli in the sputum, or both. The symptoms found which ushered in the condition at the time of the positive diagnosis of the disease, were found to be almost always one of three, or a combination of one or more of these.

1. Cough, 58; (*a*) without expectoration, 14; (*b*) with expectoration, 42.
2. Hemoptysis, 24.
3. Fever, with night sweats or chills, 10.

The few cases which could not be included in this list were ushered in by an attack of grippe (4 per cent.) or tuberculous pneumonia (4 per cent.).

The other points of interest were the confirmation of a conclusion drawn many years ago.

*First.*—That the great majority of patients who apparently develop pulmonary tuberculosis after 30 years of age have had an attack of the disease before; often so slight that it was overlooked, or they recovered so rapidly, owing to climatic advantages, that they questioned whether they ever had it, and unless a very careful history is obtained, the fact is never mentioned, or is overlooked, and the condition for which they come under observation is believed to be the beginning of their pulmonary trouble. It was found that 20 of the 100 patients had unmistakable evidence in their histories, or acknowledged outright that they had had tuberculosis and been cured. This leaves out all the cases of pleurisy and represents people of all ages. It is a large proportion, and I believe would be much larger if the observation were confined to patients over 30.

*Second.*—The analysis also showed that three and one-third months was the average time that elapsed from the actual beginning of the disease as estimated from the history or physical examination and the first time tubercle bacilli were found in the sputum. The presence in the sputum of tubercle bacilli is not by any means an early development, in my estimation. I am aware that 100 cases is not a very large number on which to base conclusions, but the 100 are culled from between 400 and 500 cases, and selected because their histories were most complete and most accurate in detail, were more detailed histories, in fact, than would ordinarily be taken. The conclusions may not be new to the majority of you, but they will serve to impress certain facts which it seems wise for us all to keep in mind.

**Difficulties of Prognosis.**—For a number of years I have examined patients for admission to the annex of the sanatorium at Liberty, N. Y., and to the Adirondack Cottage Sanatorium at Saranac Lake. The object of the examination was to admit only favorable cases to these institutions, cases in which one might reasonably expect the disease to be arrested within six months. Naturally prognosis is difficult when based upon one examination, as is usual in these cases. Seventy per cent. of the cases examined never received cards of admission; they were too manifestly unfavorable cases. The compensation for the time given in making these examinations is the experience obtained in adjusting the relative value for prognosis of the various factors in the disease. With this object in view very accurate records were kept, both as to personal history and physical examination of the patients admitted to these institutions, and the final results of the sanatorium treatment, where possible, were recorded. All cases were arranged in three groups, numbered one, two, and three, and often on the card of admission was placed a private number: No. 1.—Very favorable case—recovery expected. No. 2.—Good case—outlook fair. No. 3.—Not a favorable case—outlook bad.

Taking 100 of the cases examined and noting the final results, I find:

No. 1 Class.—The very favorable cases; 30 per cent. were apparently cured or had arrested disease; 50 per cent. were improved, and 20 per cent. unimproved or failed.

No. 2 Class.—The good cases—outlook fair; 22 per cent. apparently cured; 44 per cent. improved, and 33 per cent. unimproved.

No. 3 Class.—The not favorable cases—outlook bad; 27 per cent. apparently cured; 36 per cent. improved, and 36 per cent. unimproved.

In looking over these figures, the thing that impresses me more than anything is that 27 per cent. of the cases I considered unfavorable, with a bad outlook, and I hesitated long before admitting to the sanatorium, were discharged "apparently cured." Twenty per cent. of the cases that I considered very favorable cases went bad and failed to make recovery.

Again taking up these cases and studying their

histories in the "light of subsequent events," I notice that many of those cases in which I had given a bad prognosis because the lesion was apparently active in different places in the lungs, either in both apices or in an apex and a base, or presented active constitutional symptoms, were discharged "disease arrested," or "markedly improved." What I diagnosed as active processes, cleared up under favorable climatic conditions and left the original localized lesion only to be dealt with, and unfavorable constitutional symptoms quickly ameliorated under climatic advantages. Again I notice in the histories of the bad cases that apparently recovered, the remark "good stomach," "digestion normal"—this fact seemed to outweigh unfavorable local conditions. I find that a number of cavity cases presenting apparently unfavorable constitutional conditions recovered, and I also notice, as would be expected, that it took them a very long time to accomplish this relative cure. In analyzing the 20 per cent. of what I took to be favorable cases that remained stationary, or did not improve under sanatorium treatment, I confess I am at a loss to account for the result. Studying their histories and the result of the physical examination again, I can see no reason why they should not recover. Most probably the 20 per cent. represents the result of some personal idiosyncrasies, or possibly the personal equation of the examiner.

The following facts have especially aided me in estimating a prognosis in pumonary tuberculosis:

1. The general vitality of the patient based upon his appearance; his history of generally good health; a good family history, especially the history of long-lived ancestors.

2. The age of the patient. Between 25 and 30 the prognosis seems to be especially favorable, but it is always important to make sure from the history that you are not dealing with an old and healed tubercular lesion which has been temporarily quiet. In such cases the outcome is somewhat in doubt.

3. The character, intelligence, and especially the disposition of the patient, are *very* important factors in prognosis. I have noticed it over and over again. People who are cheerful, not self-centered, but buoyant, sunny, and apparently without nerves, get fairly well, when we would have said their case was absolutely hopeless.

4. Good digestion is naturally a very favorable sign, but I have found that many with apparently bad digestion can be so directed as to diet and are so improved by change of scene, that with the use of suitable cathartics their digestion becomes fair. Before this factor can be an element in prognosis, we must be in a position to know exactly the stomach condition.

5. Whether one lung or more than one is involved does not seem to be such an important element in prognosis as some would have us believe, though it would certainly take longer to get well when more than one lobe is involved. I find in a large number of cases that recovered, the majority had more than one lung involved.

6. Fever, hemorrhages, expectoration, and tubercle bacilli in the sputum, are of little value in prognosis, unless the case has been watched for a long time, and much beside is known.

**Analysis of Fifty-five Cured Cases of Phthisis.**—Another series to which I will ask your attention represents 55 cases of "cured phthisis," and an analysis of these would suggest two or three conclusions which, as far as I know, have not been developed by writers on tuberculosis. These cases have been discharged from the sanatorium at Liberty, N. Y., during the past two and a half years as "apparently cured." The present condition of 44 of the 55 has been carefully ascertained, and it has been found that all but two are continuing apparently well, living in their home climate and attending to their daily occupations; so the "cure" can be said to be established. Very accurate and complete histories of these cases, most painstaking details as to the beginning of trouble and the various stages of local condition were kept at the sanatorium. They were not first-stage cases, but the ordinary class, with the disease thoroughly established; in fact, 26 of the 55 had both lungs involved, and two-thirds ran temperatures during the first one or two months after going to Liberty. What was there about these cases that made them get well, when a large number under similar local conditions and with no more pulmonary involvement, only improved, or utterly failed to recuperate, is the question naturally facing one with interest.

*First.*—The average age of these cured cases was high—twenty-nine. Only five were under twenty. Age seems to furnish a resisting power to the inroads of the tubercle bacillus, and it is certainly an element in prognosis, the period of life at which the disease first manifests itself. Tuberculosis in advanced life, from the clinical aspect, can be treated almost as another disease. While curator of Bellevue Hospital, I was impressed during the post-mortems on old people, of which we had a very large number, how many had pulmonary tuberculosis not recognized during life.

*Second.*—Another fact, and more important, seems to be the long-lived ancestors of these cured cases. Unfortunately, only in 47 of these 55 cases was it possible to obtain very reliable histories on this point, but of the 47, 31 had both parents live to pass sixty, and fourteen had one parent live to be older than sixty. Only one had both parents die under sixty. When I noticed these facts it prompted me to start similar inquiries into 50 other cases, who were under the same favorable conditions, but who did not improve. Here are the results:

Taking the same number of cases, 47, living under the same conditions, who did not improve, only 16 had ancestors who lived to be over 60. This is a marked contrast to the 47 cured cases, 31 of whom had ancestors who lived beyond 60. Of the unimproved cases four had both ancestors die under 60, while in only one of the cured cases did this occur.

I have always felt, in making prognoses in pneumonia, that the fact of long-lived ancestors was a more important point to ascertain. It is the only guarantee we have of inherent vitality and resisting power in the patient. I have had favorable decisions based upon this fact so often borne out in apparently desperate cases by complete recovery, that I have come to regard it as more important than ever. In what proportion people with long-lived ancestors stand chances to recover from tuberculosis under favorable conditions, is still to be noted, and I believe the facts ascertained will be of value in prognosis here as in pneumonia.

*Third.*—Another point of interest is that it took about the same number of months to arrest the disease in these 55 cases, as the disease had been in progress before the patient began with climatic treatment, analyzing, of course, the histories with great care to learn the actual inception of the disease. It is usually thought to take about twice as long to effect a cure as the time the disease had been running, even in most favorable cases. While some cases in this list of fifty-five took over

a year and a half to get well, the average was only seven months. The average time the patient had the disease before seeking climatic advantages was seven and three-fourths months. This makes an average of a year and two and three-fourths months from the beginning of the disease before the "cure" was established. This may seem a short time to some, as it did to me, but a careful reanalysis of the cases showed positively, in this set of cases, at least, that fourteen and three-fourths months was the average time.

*Fourth.*—Family history did not seem to be such an important factor. Nearly half had a tuberculous family history (24 of the 55).

**Length of Life Among the Poor After the Beginning of Pulmonary Tuberculosis.**—It is no new thing to say that the majority of cases of pulmonary tuberculosis occur among the poor in our large cities. These people have few hygienic advantages, and are usually unable to stop work until they drop, one might say, in the traces. As we see them in our large public hospitals and study their histories, we are brought face to face with the fact that in very many cases the disease has been developing for years—often with periods of prolonged quiescence, but still always present and menacing. We wonder how these people have been able to continue work and support themselves and their families. It sometimes seems as if many of them become physically accustomed to the inroads of the bacillus and resist the disease in an entirely different way from people on a higher social scale, but of less hardy history. During nearly twenty years' service on the staff of two of the large public hospitals of New York I have often had opportunities to watch the same cases for many years. Certain patients would enter the hospital for a few weeks or months during an acute exacerbation of the disease, which would quiet down under rest, care, and good food, this change doing more for these cases than climate, drugs, and constant watching accomplished for the rich. They would go back to their work, and in time again reenter the hospital with a new tubercular outbreak. This same circle keeping up for years, as is seen so often in cardiac and renal cases in the public hospitals. Endeavoring to get some idea how long the above class of patients is able to resist the inroads of pulmonary tuberculosis, I started the following study, going over the autopsy records of Bellevue and the New York hospitals, and picking out the cases where the pathological findings showed that the person had undoubtedly died from pulmonary tuberculosis gave me a definite date for the ending of the disease. Then consulting the records and histories of these cases, and ascertaining from their past history at what date the first evidence of pulmonary trouble began, gave me the second date. I now had the date of the beginning of the trouble and the end, and from those facts the time intervening could be readily ascertained. All cases in which the histories were not perfectly plain as to the time of the beginning of the lung trouble were discarded. I have been able to collect in this way 220 cases, and have divided them into two classes: (1) Cases of chronic pulmonary tuberculosis; (2) Cases of acute pulmonary tuberculosis (miliary or pneumonic). I have added this second class as of interest, for I have not seen stated the average length of time for the duration of acute tuberculosis. These acute cases include patients of all ages—infants, young children, and adults—cases of acute miliary tuberculosis, and acute tuberculous pneumonia.

The results of the two classes are as follows:

1. Chronic pulmonary tuberculosis, 128 cases; average duration of the disease, 1 year, 2 months, and 3 days.

2. Acute pulmonary tuberculosis, 112 cases; average duration of the disease, 2 months and 4 days.

These results are not final or of absolute value, but they serve to subbest a line of inquiry helpful for future investigation, and serve to show that the average time the poor are able to resist the fatal issue of the disease, with no advantages of care, rest, or good food, is a little under two years.

## SUGGESTIONS FOR REDUCING THE PREVALENCE OF SUMMER DIARRHEA IN INFANTS.*

By THOMAS S. SOUTHWORTH, M.D.,

NEW YORK.

ATTENDING PHYSICIAN NURSERY AND CHILD'S HOSPITAL, NEW YORK CITY CHILDREN'S HOSPITALS AND SCHOOLS, PHYSICIAN OUT-PATIENT DEPARTMENT BABIES' HOSPITAL.

The constant and unnecessary waste of infant life which culminates each year during the heat of summer in the deaths from the various types of diarrhea, renders the topic of this evening's symposium one of more than usual interest. I have said that this waste of potential life and energy culminates in the summer, and I have a deeper and more serious thought in mind, for I believe that as members of the medical profession at large we are indirectly responsible for a considerable proportion of this mortality. I make this statement with full appreciation of its seriousness, because more than fourteen years of study of these problems, close to the people, have definitely impressed upon me the fact that many of these deplorable deaths are due to factors which are preventable.

Only a small and almost insignificant proportion of the deaths from summer diarrhea occur in children who have been rightly fed and who enter upon the hot months with properly nourished bodies and good digestive powers which have not been overtaxed. The breast-fed infant rarely suffers. The large majority of those under one year of age who succumb to these affections are puny, ill-nourished, anemic or rachitic infants, artificially fed, who seem marked for destruction during the first continuous heated term. Where lies the responsibility for their condition? Surely not wholly upon the parents, since but few of these have failed to consult a physician at some time, for despite even ignorance and poverty, the love of their offspring is strong in all classes. Can it be that the responsibility rests heavily upon the physician whose duty it was to look beyond the present and the minor ailment for which he was consulted, and to see with the eye of experience the inevitable outcome of the present methods of nutrition if persisted in, and to impress upon the mother the dangers which must surely confront her child?

The child which dies from diarrhea, dies, as a rule, just as much because of a previously lowered resistance of its body as from the disease itself. This is why the line representing the monthly mortality from diarrhea rises sharply to its apex in July, the first hot month, while that of August, equally hot or hotter, shows a marked reduction. It is the physically unfit who are swept away by the first scorching breath of summer, and the pity of it is that much of this sacrifice could be prevented.

The measures of prevention against summer diar-

*Read at a meeting of the East Side Physicians' Association of New York.

rhea, such as fresh air, daily bathing, and pasteurization of the food, which are to be made use of during the period of greatest prevalence, are fairly well outlined in our text-books, and are reasonably familiar to most practitioners, but the truly effective prophylaxis of such morbidity and mortality should date from the birth of the child. Why are so many infants bottle-fed to-day? Why is this substitute nutriment which statistics show increases nine-fold the danger from fatal diarrheal disease becoming commoner every year? Is it because of modern social, economic, and educational conditions as some would have us believe, or is it because of an overweening confidence in the efficacy of infant foods and modern adaptations of cow's milk to replace breast milk, which nature ordained for the infant, and for the unnecessary rejection of which she exacts yearly the blood penalty of countless hecatombs of innocent victims. I have raised my voice before in protestation against this ignorance on the part of the parents and neglect on the part of the profession, and I cannot refrain from lifting it up again in connection with this subject, since it requires only ordinary intelligence to grasp the fact that if over 90 per cent. of the deaths from gastrointestinal disturbances occur in bottle-fed infants, many, nay a large majority of these would not have died from this cause had they been nursed. It is safe, therefore, to assert that the surest protection against the death of an infant from summer diarrhea, lies in normal breast feeding. Do we all appreciate this and stop to consider the possible cost, when we supinely acquiesce without protest in the careless and unthinking determination of the mother to rob her own child of its birthright and place its life remotely but none the less certainly in greater jeopardy? But great as is the duty of the physician to urge upon the mother the nursing of her infant, greater still is his duty, because the opportunity presents itself more frequently and is almost equally often neglected, to instruct the mother how she may best nourish and care for herself, in order that she may be able to continue to satisfactorily nourish her child. Why do so many mothers bring their babies to me at the Out-Patient Department of the Babies' Hospital with the story that they weaned their babies by the doctor's advice without any intelligent or conscientious effort to restore a supposedly poor or failing breast milk, and saddest of all, when the simplest inquiry reveals the fact that bad nursing habits and not the milk were at fault. A like negligence and disregard of well-established principles in the case of a simple fracture involving none of the danger to a human life, would furnish grounds for a suit for malpractice. Why, again I ask, should nursing be abandoned simply because there is not quite enough of the breast milk for the infant's needs. Would it not be arrant folly because a half loaf of bread were not sufficient to satisfy a needy family, to throw it away and go in weary search for a whole loaf, made of less digestible materials? Even partial breast feeding furnishes an important measure of protection to the child, and, in addition, it is a resource in reserve in time of urgent need. The practitioner who has not made use of concentrated corn meal gruel for the nursing mother does not realize what can be accomplished with a deficient mammary secretion.

Both in private practice and in hospital and dispensary work I begin in the early spring to protect children against the summer; rachitic children receive proper attention; anemia is treated energetically; diets are regulated; recurrent autointoxication is guarded against, even the slightest subacute or persistent gastrointestinal irregularities are corrected. Thus, and only thus, is the ounce of prevention placed upon the long arm of the lever so as to render unnecessary the often ineffective pound of cure.

The educated classes have already been trained to recognize the dangers lurking in impure milk. It may take a little longer with the uneducated and foreign population, but it can be done. No class of people are more unreasonably tenacious of ideas once acquired than they. Teach them as our predecessors did, that the milk of one cow is best, and it takes decades to eradicate this belief in accordance with our better understanding of the subject. Teach them that safety is only to be obtained by the sterilization of milk, and they will boil the living principles out of all milks, and at all seasons of the year. Teach them as you can and may, that in clean "certified milk" lies a still greater safety, and an overwhelming popular demand will force all the dealers to supply it, for the present refusal of some of the larger distributors to handle it would then spell for them financial loss. Such measures as are now being enforced at the farms by the Board of Health are excellent, and should be supported and encouraged, but the resistless force which shall make these changes permanently effective, must come from the consumer. Competition is keen in modern life—if the public demand little, they will assuredly get less than little, but if they intelligently and persistently demand much, they will at least secure some measure of what they seek. It seems but yesterday that I sat beside Dr. W. H. Park at a dinner of the Hospital Graduates' Club, when he asked with apparent misgivings whether, if milk could be placed on the market with a bacterial count below 100,000 per c.c., we thought that a demand could be created for it. We told him yes, and to go ahead. To-day, only three years later, the daily sale of "certified milk" in this city is already 6,300 quarts, and of "inspected milk" 2,600 quarts. After January 1, 1906, the total will be 10,780 quarts per day or nearly 4,000,000 quarts per year. What may we not do in another year, five years, ten years, not only by concerted action, but still more effectively by individual effort.

The mothers of this city believe that the bottled milk of a certain firm is the best milk obtainable, and they name it to one who inquires with conscious pride. They believe it to be the best milk because we have so taught them. Yet that firm has steadily refused to institute inspection of its farms, and buys milk from all sorts of sources. What they sell is just a good full standard old-fashioned dirty milk. It is in our power to increase the sales of "certified milk" until all dealers must have it. But "certified milk" is rather more expensive. Yes. It costs more to produce it clean and to keep it cool during shipment. Cost always advances with quality. "Certified milk" costs at present 12 cents a bottle. Ordinary milk in bottles sells for 8 cents. The extra cost of "certified milk" is 4 cents per day—scarcely prohibitive for those at all able to buy 8 cent milk. Four dollars cover the extra cost for the hundred days of summer. Better to pay this to the milk man, if thereby we may cheat the undertaker. It is not a difficult matter to persuade the mothers to purchase a clean "certified milk" if one states plainly and simply its advantages over common bottled milk. I find the mothers ready and anxious to secure the best for their infants.

Let us, however, cherish no illusions in our own minds nor create any false impressions among the laity concerning "certified milk," as furnishing any sort of infallible charm against summer ills. The use of certified milk allows us to begin our measures for the protection of the child, where they should

begin, with a clean milk instead of a germ and toxin-laden one, which half defeats our purpose from the start. It renders no iota less necessary the careful modification, clean handling, pasteurization, rapid and immediate cooling of the milk, and its maintenance at a low temperature until the food is consumed.

It is true that one sees in an Out-Patient Department like that of the Babies' Hospital chiefly other men's failures in infant feeding, but as they come to me from all sections of the city, they furnish some sort of criterion by which to judge of the average standard of familiarity with the accepted methods of milk modification and feeding. It is the exception for an infant to be brought to us, even among those who are brought to us for matters entirely independent of their nutrition, where glaring errors do not exist, and radical changes in method and management are not necessary to bring them up to proper standards.

Some of the commoner and the most fundamental of these are as follows: Young infants at birth or after a disturbing succession of "infant foods" are put upon too strong modifications, in which the milk is not sufficiently diluted, and the resulting percentages of proteids too high. Disturbance naturally ensues or there is failure to assimilate with stationary or decreasing weight, and the child is forthwith declared unable to digest cow's milk. Again, the two-hour feeding interval suitable for easily digested breast milk during the first two months of the infant's life, or for the weaker modifications of cow's milk, is continued indefinitely while the amount of the cow's milk is increased in the mixture, despite the well-established facts that cow's milk forms curds requiring longer stomach digestion than breast milk, and that the more complex become the compounds formed from the milk by the developing digestive secretions of the stomach, the longer should be the feeding interval to allow for complete emptying of that viscus. Short and irregular feeding intervals work havoc with an otherwise good digestive tract.

Besides these improper proportions and intervals the quantity also given at each feeding is frequently unsuitable. The higher the degree of malnutrition and especially of malassimilation, a type of cases in which the infant actually is starved from overfeeding, the higher is pushed the quantity, to quiet the pangs of indigestion or possibly, also, of hunger, resulting from failure to absorb the already overabundant nourishment. An overfilled stomach cannot functionate properly. There should be some reasonable relation between the quantity of the scanty digestive secretions of the infant's stomach, and the amount of the food ingested. Little wonder then, that when this is disregarded, the partially and imperfectly digested masses finally ejected into the intestine lead so frequently to the development of diarrhea.

Perhaps one of the most important factors in causing gastrointestinal disturbances is the failure to establish and maintain a proper low temperature of the food after it has been prepared. In no other respect, I think, are the best intentions of the physician so often defeated and rendered of no avail. The best milk always contains some bacteria ready to multiply by myriads if its temperature is allowed to rise. Pasteurization and even sterilization as ordinarily performed, although of inestimable value in hot weather, when followed by proper precautions, do not destroy all the bacteria and especially the more resistant spores. Pasteurize or sterilize such milk and place it hot or even warm in the usual ice box, and it maintains its heat long enough to start again the growth of the unkilled germs. Rapid and immediate abstraction of the heat by surrounding it with running water, alone properly rounds out the process.

I have detailed elsewhere* the valid reasons why a partially soured milk in which the lactic acid gives as yet no visible warning from curdling of the casein, forms tougher curds and is consequently more indigestible than even a fully soured milk, such as few to-day would have the temerity to give an infant knowingly in summer—unless we could carefully control its preparation. Aside from putrefactive changes this danger from partial souring of the milk, whether heated or unheated, may occur not only from insufficient cooling in the ice box, but from ignorant and careless exposure of the container to room temperature for considerable periods, from the rewarming of partly used feedings, from the carrying about of feeding bottles during prolonged excursions, and from the almost criminal use of bottle cosies, which save the tired parents at night at the expense of the child.

In my boyhood in New England, much was heard of the dangers of a child's second summer. Why of the second rather than the first? Because breast feeding was the rule with its immunity to this class of difficulties, while the period of weaning and the introduction of table food presented new dangers. The feeding of the younger children in the tenements of this city is a reproach to the medical profession. We are not doing our duty. We do not supervise these matters as we should. Why are tea and coffee, useless and injurious stimulants with no food value for the young, the rule rather than the exception in the diet of the child as soon as he can sit at table? Why are these same children given a little of everything digestible and indigestible, which the rest of the family eat? Many of these are substances which pass undigested through the intestinal tract, a fertile source of an irritative diarrhea, so often the forerunner of more serious conditions. I tell you that these things are so because we as the physicians are too indifferent, too busy, or too careless to instruct the parents of the families we enter.

The medical profession is also largely responsible for the continuance of many of the popular beliefs and superstitions. It is so much easier to tacitly accept the theory of some opinionated member of the family as to the cause of the trouble than to combat the error. Why, in this enlightened age should the young mother still advance as her excuse for neglecting a serious diarrhea in its earlier stages, that the child was teething, as though diarrhea were the normal accompaniment of the eruption of the teeth. What part, if any, does teething play in the etiology of diarrhea? We have swung the full round of the circle from allowing it to be a prime cause, to claiming that it has no disturbing influence. Neither position is correct. Teething alone does not cause diarrhea. It is not a natural or normal accompaniment. But when the nervous system is also disturbed by a combination of depressing heat and uncomfortable gums, an overtaxed digestion which has thus far barely struggled along upon the ragged edge, frequently gives up in disgust. The difficulty has been and is primarily with the food and the digestive tract.

We must impress upon the mothers that a child is not always hungry when it cries; that hot weather calls for less food and weaker food, at longer intervals, with more abundant giving of water. Fat is required in the food in winter in sufficient quantity to furnish fuel to maintain the body temperature, but in summer and in hot climates this may be wisely re-

*"The Digestion of Caseins, and Its Relation to Certain Problems in Infant Feeding."—MEDICAL RECORD, March 4, 1905.

duced. We must not forget that a very appreciable amount of energy is expended by the body in throwing off, excreting, the superfluous body heat which is formed. This is no slight additional tax upon the powers of the organism, and if unduly increased by overfeeding contributes to the exhaustion and lowers the tone of the digestive system.

Cow's milk, much as it deserves our attention as a frequent source of infection, is not the only carrier of germs into the infant's intestinal tract. What of the sucking nipple, that fraud upon infant credulity, that almost constant appurtenance of the fretful marasmic child, moistened in the bacteria-laden mouth of the attendant to render it more acceptable, dangling against dirty clothes from a dirty string, or reposing temporarily upon dusty shelves and tables, carried in dirty pockets, rolling upon filthy floors and sidewalks and then wiped, perfunctorily if at all, before being reinserted in the mouth of the infant. The physician may concern himself to order sterilization of the milk and scalding of the feeding bottles, but this germ-laden horror of lethal tendencies is tolerated without a protest. A large cluster of these apples of Sodom which turn to dust if not to ashes in the mouth, reluctantly surrendered by the parents hangs prominently upon the wall of my clinic as a warning that I will not, knowingly, begin or continue the management of any infant unless this practice is discontinued. Impossible to prevent their use, do I hear some one say? Not if the mother is made to understand the dangers. Where are the old germ-laden tubing extensions for the nipples of nursing bottles? They are gone—banished even from the drug stores, because they are no longer salable, and we, as physicians, accomplished this by education of the masses, and we can do more and yet more, if every individual among us does his day's work well. For the physician's day's work, even if he sees a child but once, is to seek out and correct errors in nutrition, to combat popular misapprehensions, to further the use of clean milk, to warn mothers that at the very beginning of loose movements in summer, they should stop the use of cow's milk in any form, clear out the bowels with castor oil, give water or cereal gruels only, and send promptly for the physician, since delay is so often fatal. Thus, and thus only, may efficient prophylaxis be established, infant mortality in summer be reduced, and the physician have the satisfaction of knowing that he has done his full duty. Patient, painstaking, personal instruction of the masses will alone accomplish the end which we are seeking.

807 Madison Avenue.

## THE HISTORY AND BASIS OF DIETETIC METHODS IN TYPHOID FEVER.*

By JOHN BENJAMIN NICHOLS, M.D.
WASHINGTON, D. C.

At the present time a diet consisting chiefly of milk, with other fluids as accessories—"liquid diet"—is almost universally used in the management of typhoid fever. The firmest faith and confidence in the adequacy and superiority of this diet are entertained; it is enforced unvaryingly and indiscriminately in all cases of the disease; and the gravest fears are held of departures from it or of the use of solid food. So firm and fixed are the general convictions on this doctrine, that it is regarded as impregnable and final, and dissent from it is viewed as folly or heresy.

The purpose of this paper is to present the results of a study of the basis on which this practice is founded, considering, first, the historical development of the present practice, and, second, the principles advanced in its support.

Prior to the time when typhoid was definitely distinguished from typhus and other fevers as a separate disease, the ideas of the medical profession as to the causes, nature, and classification of the febrile diseases were very hazy and confused. By the middle of the eighteenth century it had begun to be appreciated that there were different varieties of the continued fevers, such as, in the terms of those days, inflammatory fever or synocha, typhus, putrid fever, nervous fever, synochus, etc. The distinctions drawn between these varieties were, however, extremely vague and dim, their visceral lesions were unknown, and in the contemporary literature and practice they were for the most part considered and jumbled together under the general and common head of "fever" or "continued fever."

The question deemed of vital importance in the pathology and therapy of fevers in those days was as to whether they were essentially inflammatory or asthenic in character. Inflammatory or phlogistic fevers were those depending essentially and primarily on local or general inflammation or excessive action of the heart and arterial system; they were of sthenic type, characterized by overexcitement, and called for vigorous lowering and depleting measures—"antiphlogistic treatment"—by bleeding, purging, emesis, starvation, etc., to subdue the excitement. In the asthenic fevers an adynamic element was recognized as dominant, and stimulant treatment was correspondingly regarded as appropriate. Many, however, held that the appearance of asthenia in fevers was deceiving, and that the symptoms observed were really due to overexcitement. The profession was pretty well agreed that inflammatory diseases required vigorous antiphlogistic treatment and asthenic conditions required stimulation; but there was difficulty and question in the practical application of these principles, the determination whether particular cases or diseases were essentially inflammatory or asthenic arousing endless speculation and discussion. In the treatment of the continued fevers there were thus two squarely opposed systems of practice, the antiphlogistic and the stimulant; the advocates of each reproached their opponents with having caused the loss of untold lives by their vicious methods; and strenuous controversies were waged as to the employment of bleeding, purgatives, emetics, blisters, food, tonics (cinchona), stimulants, etc. On the whole, the antiphlogistic habit was firmly implanted in the professional mind and strongly influenced the practice even of those who did not concur in the phlogistic theory of fevers.

In the seventeenth century, Thomas Sydenham (1624-1689), the leader of English medicine at that time, followed a vigorous antiphlogistic plan in the treatment of continued fevers, bleeding copiously and repeatedly. For diet he gave "water-gruel, barley-gruel, and the like," also a few spoonfuls of broth two or three times a day, and beer.

During the eighteenth century, and down to about 1815, the mode of treatment of continued fevers was stimulant or mildly antiphlogistic, the adynamic element being freely recognized. Bleeding and other vigorous depleting measures were regarded with disfavor, unless at the very onset of the disease or in distinctly sthenic cases or stages of fever. What was considered a liberal amount of food was allowed, of exclusively vegetable character. Animal food of all kinds was rigidly excluded from the dietary, as it was believed to increase

*Read before the Clinical Society, Washington, D. C., March 13, 1905.

the body heat, to be a source of excitement, to be too great a burden on the digestive powers, and to putrefy excessively. The prohibition of animal food embraced not only meat, but also eggs, broths, beef tea, meat extracts, etc.; and so deeply was the professional mind imbued with the idea of the essential harmfulness of animal food that a marked prejudice against even broths and bouillon persisted down to a recent date. The writers of the time for the most part say very little explicitly about the use of milk. Some condemned it; and for this they had the authority of Hippocrates, who regarded milk as objectionable in fever. There was also a popular prejudice against the use of milk in fever feeding. Some authorities, however, permitted the use, with caution and reserve, of diluted milk in small amounts, placing it between vegetable and animal food in its heat- and excitement-producing qualities.

The food employed was mainly farinaceous, in thin liquid or pultaceous form, as gruels or "ptisans" like barley water, thin oatmeal gruel, sago or arrowroot preparations, and "panada" (toast water, or toast made into a fluid mass with boiling water). Fruit juices and soft, pulpy fruits were also allowed. What was regarded as a fairly liberal amount of such vegetable food was given, especially after the first few days of the fever. In the latter period of the fever and early convalescence the farinaceous dietary was amplified by the addition of broths, diluted milk, jellies, and gradual return to animal food.

Free drinking was generally encouraged and regarded as an important part of the treatment, to dilute the blood and promote excretion. Besides plain water, drinks acidulated, like lemonade, or flavored with aromatics or otherwise, were in high favor. Two or three quarts of such drinks were given daily. In the eighteenth century, as at the present time, there were some who carried the use of water to an extreme, believing in the sufficiency of an aqueous diet, that is, the withdrawal of all other food and giving water in large amount, four quarts or so daily.

From about 1815 to 1835 or 1840 continued fevers were treated on a very vigorous antiphlogistic plan, and an extremely restricted diet was in general use.

An extensive fever epidemic prevailed in Great Britain and Ireland about 1817-1819, during which, largely under the teachings of Henry Clutterbuck, Thomas Mills, and others, the theory that fever was essentially a phlogistic or inflammatory process came into general favor, and the corresponding practice of vigorous depletion, chiefly by profuse venesection, was generally followed in these countries. A starvation regimen was enforced; the drinking of watery fluids in large amounts was encouraged, but wine and stimulants were prohibited.

In France the adoption of antiphlogistic practice during this period was due to the teachings of François Joseph Victor Broussais (1772-1838), whose writings date from 1816 and who had a strong influence on French practice for a couple of decades. Arguing from the fact that alimentary disturbances are common in fevers and many other disorders (without any knowledge of the intestinal lesions in typhoid), he taught that gastroenteritis was the primary and underlying cause and essence of manifold disorders, and especially of the various febrile diseases. So firmly did this idea become established that for a considerable period the term "gastro-entérite" was one of the principal names for typhus and typhoid fevers. The treatment of fevers practiced by Broussais and his followers in accordance with this conception of their pathology consisted mainly in copious withdrawal of blood by leeches and in starvation. The diet allowed—the "diète absolue" it was called—was practically no diet at all. All foods requiring digestion and which would therefore embarrass the supposedly inflamed alimentary tract,—broths, farinaceous food, fruits, etc.—were prohibited, broths being regarded as especially harmful. All that was allowed was sufficient drink to satisfy thirst, consisting of slightly sweetened mucilaginous drinks, or acidulated drinks like weak lemonade, gooseberry or raspberry water.

The next epoch in the history of typhoid dietetics was that of Robert James Graves (1797-1853) of Dublin, who has the reputation of having established the practice of liberal feeding in fevers. His deliverances covered the period from about 1835-1850. He rejected the phlogistic theory and antiphlogistic therapy of fevers, and believed that the current practice needlessly added the "horrible consequences" of starvation to the symptoms of the fever, and that it was "as hard to escape the physician as the disease." He therefore advocated what he regarded as liberal feeding, and so closely is his name identified with this practice that a jocular suggestion for his own epitaph—"He fed fevers"—once made by him, has become historical. This incident is thus related by William Stokes, the associate of Graves: "Once, when he and I were going through the convalescent wards, he expatiated on the healthy appearance of the patients, many of whom had gone through long fevers. 'This is all owing to our good feeding,' he said. 'Will you, when the time comes, write my epitaph, and let it be—*He fed fevers!*'" As a matter of history, it may be stated that this was not actually used in his epitaph. (Stokes, Lectures on Fever, 1874, page 328; *Medical Times and Gazette*, 1854, VIII, page 5.)

The diet recommended by Graves was as follows: For the first three or four days, water, weak barley-water, and whey. After that, mild nutriment was to be used, his preference being for well-boiled gruel made of groats, with sugar and lemon juice; also thin panada. Of the gruel and panada a spoonful of either was given every third hour. In the middle and late stages of the fever mild animal jellies and broths (preferably chicken broth) were given. Arrowroot was also allowed. Fruits were to be avoided. Food was to be given in the daytime only and not at night. Too much drinking was not permitted. This diet was much the same as the farinaceous diet used in the eighteenth century, which was therefore reintroduced by Graves. Judged by present dietetic standards, it can hardly be regarded as a very generous diet; and if it was considered liberal in Graves's time, the dietary previously in use must have been scanty indeed.

It was during the latter half of Graves's life that the true pathology of typhoid fever was discovered and the disease came to be recognized as a distinct affection, different from typhus. There had previously been glimmerings of clinical differences between different kinds of continued fevers, as in John Huxham's distinction between "slow nervous fever" (typhoid) and "putrid, malignant, petechial fever" (typhus) in 1750, and the synochus and typhus of William Cullen in 1769; the intestinal lesions in cases of typhoid had also been observed in a few instances; but the morbid anatomy of typhoid fever was first put on a substantial and enduring basis by Pierre Charles Alexandre Louis (1787-1872), whose classical researches on this subject were first published in 1829. The continued fevers of France that came under Louis's observation, however, were exclusively typhoid, and not

having had a chance to become familiar with typhus he did not realize that there were two distinct diseases and he regarded the lesions observed by him as pertaining to typhus. In America, also, the prevailing fevers were mostly typhoid; but typhus occasionally occurred, and it was through an opportunity of observing an epidemic of the latter that William W. Gerhard of Philadelphia, who had become familiar with typhoid in Paris, was enabled, in 1837, to announce definitely that typhoid and typhus were two distinct diseases. This, the first clear elucidation of the distinctions between these two diseases, based on sound pathologic principles, stands to the credit of American medicine; and the distinction very soon became generally recognized in the United States. In Great Britain and Ireland, however, the prevailing fever was typhus, and typhoid was so exceptional that the intestinal lesions occasionally seen at autopsy and described by the French writers were regarded as secondary and occasional complications of typhus. It was not until a series of papers on the subject was presented by Sir William Jenner, in 1849-1851, that a clear understanding of the distinctions between typhoid and typhus was finally attained by British physicians.

The recognition of the distinct character and intestinal lesions of typhoid fever at first had no influence on the dietetic management of the disease, and a farinaceous regimen much as reintroduced by Graves was generally followed down to the late sixties and the seventies of the last century. The medical manuals of this period specify the use of gruel, arrowroot, panada, and similar farinaceous food, with refreshing drinks flavored with fruit juices, for typhoid feeding. Some, but not all, of the writers also admitted broths, jellies, diluted milk, and the like. As late as 1874, Liebermeister, in his article on typhoid fever, in Volume I of von Ziemssen's "Cyclopedia of Practical Medicine," argued for a carbohydrate or farinaceous diet, and against a proteid or animal diet, on much the same grounds as had been previously adduced for centuries.

During the late sixties and the seventies of the nineteenth century, the present liquid diet, consisting chiefly of milk, gradually came into practically universal use. I have been unable to find any special papers or authorities that led to the abandonment of the farinaceous and adoption of the milk regimen; the change was apparently a process of gradual evolution, and in the literature since 1875 or 1880 the milk diet has been almost unanimously advocated.

At the present time, while a few authorities favor a more varied and more generous diet, nearly all the leading manuals on the practice of medicine prescribe rigid adherence to the milk and broth diet, and urge the dangers of solid and even of soft food in typhoid fever. Various arguments are presented in favor of this practice, the validity of which may be briefly examined. A characteristic example of the way in which the subject is usually presented, and one embodying most of the points involved, is afforded by the following passage from James H. Hutchinson's article on typhoid fever in Pepper's System of Practical Medicine, 1885 (Volume I, page 323): "The food must . . . be not only nourishing, but also readily digestible, and not likely to create irritation in its passage through the intestine. All solid food should therefore be excluded from the dietary of the patient as long as the fever lasts. . . . Milk as an article of diet is unquestionably to be preferred to all others in typhoid fever."

The general premises that the typhoid diet should be nutritious, digestible, and innocuous are generally agreed on; but in the actual application of these principles arise differences of opinion and practice.

Theoretical considerations which have an apparently reliable basis indicate that the daily diet of an average-sized typhoid-fever patient should yield about 100 grams of proteid and 2,000 calories of energy, a quantity that would be furnished by three liters (or quarts) of milk. As under the present system the amount given daily is only one and one-half to two liters of milk, or its equivalent, the legitimate question arises whether the standard of nutrition generally followed is not materially inadequate, and to what extent the conditions presented by the ordinary typhoid case may be due to partial starvation and what to the disease proper. Moreover, the fact that patients are deliberately compelled to suffer for weeks the distressing pangs of hunger, which might be taken as a call of nature for more food, without any attempt at relief, is another reason for suspecting that typhoid patients are still underfed.

No one questions the necessity for digestibility of the food in typhoid fever. There may be question, however, as to the relative digestibility of different kinds of food, and as to the digestive powers of the patients. The assertion is often made that in typhoid fever the digestive powers are entirely or almost entirely abolished; this belief appears, however, to be based more on vague impressions than on accurate measurements, and is probably far from the truth, since I have found by analysis of the published metabolism investigations in cases of typhoid fever that the average falling off of digestion is only five to ten per cent.

There is also no question as to the proposition that the food should be such as to cause a minimum amount of harm under the special intestinal and other conditions present in typhoid fever. The degree of innocuousness or harmfulness presented by different foods is a matter to be determined for each particular article and the idiosyncrasies of each individual patient. Various criteria as to innocuousness are laid down by the upholders of the present methods, such as minimum fecal residue, nonfermentability, etc., but the food articles now in use seem to be no more free from objections of this sort than articles that are forbidden.

From time immemorial solid food has been regarded as totally inadmissible in fever. In the literature, however, this doctrine is laid down dogmatically and without proof, as if it were self-evident, and did not require critical consideration and demonstration. A great deal is taken for granted in this assumption, and if it is true it is certainly worthy of being established on scientific dietetic principles rather than on dogmatic assertion or vague impressions. It is my own belief that soft and solid foods are not intrinsically contraindicated in typhoid, and that a critical consideration of the physiologic principles involved will show that they are no more objectionable, and in some respects are less so, than liquid foods. The idea seems to be that solid food is less digestible than liquid food, more irritating to the intestines, goes through the alimentary canal in a more solid and bulky form, or in some occult manner augments the disease processes in a way that a corresponding amount of liquid food will not. These suppositions need the test of criticism. Well-divided solid proteid food is as easily digestible as the liquid proteid of eggs or milk; both kinds of proteid have to go through exactly the same digestive process before they can be absorbed. Meat and eggs are certainly no more, rather much less, provocative of intestinal indigestion and fermentation than milk. The solid

matter of meat, eggs, and bread leaves much less fecal residue than does that of milk. The idea that solid food will remain solid, and liquid food remain liquid, in their passage through the alimentary canal is contradicted by common experience; since proper and properly prepared solid food enters the bowel in pasty or practically fluid form, while milk, regarded as the ideal liquid food, enters the bowel in solid masses.

That milk is self-evidently the best food for adults is open to question. If it were necessary to limit the diet to a single article of food, milk would unquestionably be the best, and it is one of the most important ingredients in any diet. It contains all the requisite food elements, proteid, fatty, carbohydrate, and saline, and is as rich in energy value as most fluid foods. It presents, however, certain disadvantages, as coagulability, fermentability, bulk, etc., and while it is a natural and complete food for infants it is not adapted to exclusive nourishment of adults except in amounts (over three liters or quarts per day) that are practically prohibitive. The necessity for practically confining typhoid diet to the one article, milk, however good a food it may be, and for excluding other articles that would afford greater variety and more nourishment, is not obvious. It also does not necessarily follow that because milk is fluid it is on that account more easily digestible, less irritating to the bowels, or leaves less fecal residue.

The argument is often offered that the superiority of the present dietetic methods in typhoid is shown by universal experience and approval. The appeal to universal practice and experience on its face seems a strong argument, yet a consideration of the history of medicine shows that it is an argument to be accepted with great reserve. There have been scores of theories and systems and methods of practice that for a time enjoyed universal approval and claimed justification on the ground of the results of general experience, which nevertheless in the end were found erroneous and were utterly discarded. What general experience may fairly be claimed to have demonstrated in the matter of typhoid feeding is this, that the present milk diet, one of medium nutritiousness, gives better results than any of the more restricted diets previously in use. An equally general trial of a diet even more liberal than the present one might give a showing of results better still. The claim that experience has shown the essential danger and inadmissibility of a diet more generous than the present one, or of the use of solid or soft food, is open to this objection, that such liberal feeding has never been given widespread trial, and there has been no general experience with it to show its inadvisability. The grave fears once entertained of the use of milk and broth were shown by actual trial to have been groundless; and the present similar fears of soft and solid food might likewise, on trial, prove to be unfounded. The occasional occurrence of *febris carnis* or even of a relapse from improper feeding, does not constitute a logical demonstration that liberal diet, properly given, is intrinsically harmful.

Believing, as I do, that typhoid patients should be given a more varied and more abundant diet than is now customary, my object in this study has been, not the mere academic one of presenting the history of defunct methods, but the more practical one of attempting to throw real light on this important question by endeavoring to determine the actual worth and validity of the grounds on which the present methods have been developed. The history of feeding in fever shows a progressive advance from a starvation regimen in the direction of more and more liberal diet. Methods and foods in one epoch regarded as highly injudicious and dangerous have, in succeeding periods, come into general use, and the feared objections proven groundless. We have come to the use of a diet of medium nutritive value, but there is still room for further advance. The habit of antiphlogistic therapy was through centuries of belief and practice firmly impressed on the professional mind, and it has been with difficulty and with fearful and cautious steps that the profession was emancipated from that practice. Indeed, it is possible that vestiges of the antiphlogistic habit are still apparent in the treatment of fever; physicians no longer bleed and purge and puke their patients to death, but they still partially starve them, and practice with complacency and good faith a system that subjects the sufferers to the tortures of the most distressing hunger and semi-starvation for weeks. The present attitude of the profession on some of the points involved is also suggestive of the state of mind that prevailed during the antiphlogistic era.

The evolution of the methods of feeding in typhoid fever seems to have been largely fortuitous and empirical, and the present practice has not been established on or subjected to the critique of scientific dietetic and physiologic principles, as has been done, for instance, in the matter of infant feeding. I have presented some reasons tending to show that the arguments advanced in support of present methods and doctrines are in some respects fallacious and questionable. A fuller and more detailed study of the subject I have presented elsewhere (in a paper read before the Medical Society of the District of Columbia, October 5, 1904, published in *American Medicine*, May 6, 1905); in the present paper I have endeavored to express the grounds of my belief that finality has not yet been reached in the methods of feeding in typhoid fever, and that a reconsideration and revision of the matter by the light of modern scientific dietetics is called for.

## ANIMAL REMEDIAL PREPARATIONS.

By JOHN W. WAINWRIGHT, M.D.,
NEW YORK.

Various glands, from freshly slaughtered sheep and other animals, employed either in the fresh state, desiccated, or as carefully prepared extracts, have within the past few years found a constantly increasing usefulness in therapeutics.

Brown-Séquard's enthusiastic claim that "all the glands of the body, whether excretory or not, supply to the body useful principles, the absence of which is felt, when these glands are extirpated or destroyed by disease," spread like wild-fire around the world, and gave the charlatans a remunerative field for humbuggery and flowery advertisements.

As a natural consequence, conservative and careful observers at first were rather skeptical in the acceptance of such sweeping statements, especially so as failure was the rule when these remedies were employed. The attention of the profession was, however, called to the subject, and not only Brown-Séquard and his associate, D'Arsonval, but the best scientific minds in the profession in every land, gave painstaking and untiring labor to a careful and systematic experimentation, which resulted in giving the materia medica some of its most positive remedial agents.

The striking effect of the employment of the thyroid gland, or a carefully prepared extract thereof in myxedema, is indeed an ideal illustration of Brown-Séquard's theory. We know that myx-

edema is caused by absence or disease of the thyroid gland, and, therefore, the result of the withdrawal of the secretion of the gland. In cretinism or congenital absence of the thyroid, or after operative removal of the gland, a similar condition exists. No form of treatment gave any material benefit to these conditions up to the time that the extract of the thyroid was first used. Astonishing results follow its employment. All the signs and symptoms of the disease disappear, under its constant use the individual may absolutely recover his health and remain well so long as the administration of the thyroid extract is continued. As soon as it is discontinued, the previously existing symptoms gradually reappear, thus proving beyond a doubt that it is the absence of the specific principle of the thyroid gland that is the cause of the disease. Unfortunately, like striking results have not followed the employment of all the other glandular extracts. The success of the thyroid treatment has, however, led to a more thorough study of biology and the allied sciences, and we have as a consequence not only the glandular extracts, but also extracts of bone-marrow, the nucleins, etc., all of which undoubtedly have their usefulness, though as yet not thoroughly defined.

The main difficulty with the definite and scientific examination of the active principles of these various animal secretions and organs, is their minute quantity, which limits a study of their chemical nature. Their great activity—as evidenced not only by their individual specific effect, but also by other manifestations, such as tachycardia, faintness, etc., following the administration of even small doses—seems to be caused by an organic principle belonging to the class of leucomains, lecithins and protagons, etc., and when we recall that, for example, the lecithins under certain experimental conditions split up into glycero-phosphate, stearic acid and cholins, the powerful actions of which are well known, we readily see that we have certainly arrived at the borderland of a more definite science of the future.

The antitoxic effect of cholin, caused by its oxydizing action on the blood, is probably one of the very few facts beyond dispute; however, it may be wisest not to attempt to discuss any especial line of theorizing regarding the chemical nature of this complex and as yet vague subject. A short résumé of the chemical and experimental facts and deductions up to the present time may not be amiss, after first giving a short history of their pharmacology.

On account of the very rapid chemical post-mortem changes in glandular structures and secretions, the greatest care, rapidity and aseptic precautions have to be observed in their study and to insure our finding what we are looking for.

Thyroid gland and its preparations have received the greatest amount of study and renown.

The active principle of the thyroid gland was discovered by Baumann, and is called thyroidin. It contains a large percentage of iodine, but it is thought that there are also other physiologically active substances in the gland. The internal secretion of the thyroid which comprises its function is a colloid material, which is elaborated by the alveoli of the gland and carried into the general circulation by means of the lymphatics. This secretion is essential to the general well-being of the individual, for when it is absent or deficient the effects are most apparent. There are two stages of treatment for its deficiency —first, the restoration to the normal, and, second, the maintenance of this normal condition after it has been attained. In the cases in which the treatment is not beneficial at the end of two months, it will probably prove useless.

Various conflicting theories are held concerning the importance of this gland in the animal economy, as may be easily seen by a rapid review of the recent literature on this subject.

Hutchinson reports that "iodothyrin is the only active physiological constituent of the gland." As to the presence of iodine, there is no satisfactory explanation, nor is it possible to say whether iodine is essential to the activity of the iodothyrin. If it is essential, Hutchinson thinks that it is due to its peculiar organic form and not to the fact of its being iodine. As yet no specific action of thyroid on any of the organs has been proven. It has a marked effect on the general metabolism, so marked as to suggest that its influence acts through the nervous system rather than through the tissues. There is, however, no proof of this." This author "does not regard iodothyrin as an ideal antifat remedy, for its action is early destructive of the proteid tissue, and not destructive of the fat alone, or to any great extent. The question is still open as to the final disposition of iodothyrin. It may be taken up and used again, or it may be excreted, for a trace of it may be found in the urine after the administration of thyroid."

"Nursing children of mothers who were being treated by thyroid have exhibited symptoms of thyroidism." Hutchinson thinks that "these toxic symptoms of thyroid are due to some other substance, induced by the increased metabolism brought about by the thyroid." This writer "does not believe in the hyperthyroidization theory of exopthalmic goiter. He thinks that it is the removal of the parathyroids that causes the nervous symptoms generally associated with thyroidectomy. These bodies contain iodine."

Osborne sums up the physiological action of the thyroid as follows: "This secretion seems necessary for the proper equanimity of the central nervous system and perhaps nutrition and development of it, to the proper quantity of mucin that shall appear in the tissues, principally the connective tissues, to the proper organization of phosphorus for the assimilation into bone salts, and by its vasodilator power to properly regulate the peripheral circulation, thus regulating the heat loss and the normal insensible perspiration of the skin, which, if disturbed, shows on the one hand in the drying of the skin in myxedema, and on the other hand in the increased sweating in Graves' thyroid disease. This gland seems also to have some power of regulating the rapidity of the cardiac contractions. It is probably easily excited to hypersecretion temporarily by emotion, and we know it to be normally enlarged and hypersecreting during menstruation and pregnancy." The circulation of the brain also falls under the influence of this vasodilator element, stimulating it in excess, causing cerebral excitement.

The gland begins to atrophy between the ages of forty and fifty. Extreme atrophy is far more frequent in women than in men—80 per cent. of all cases of myxedema occur in women. Osborne believes in regard to Graves' thyroid disease (exophthalmic goiter) that if there is cerebral excitement, cardiac palpitation and continuous loss of weight, treatment by thyroid is contraindicated. If the disease has progressed to the next stage in which there is increased connective tissue growth so that there is a condition of undersecretion with little palpitation, no headache, while there is an increase in weight, thyroid will probably be beneficial.

Sherman reports a case of obesity in which, by means of thyroid extract, he reduced the weight of the patient about forty-five pounds. Other similar cases have been reported. Beatson has suggested treating inoperable carcinomata of the breast by the

combination of thyroid administration and the removal of the tubes and ovaries. It is thought that about 20 per cent. of these cases are benefited by this combined treatment. After the menopause, removal of the ovaries is not of so much importance. Page and Bishop report good results in these cases from the use of thyroid alone. As to the benefit of this treatment in cases of carcinomata of other organs, there is no evidence. Coppez reports "five cases of optic neuritis following the use of large doses of thyroid for obesity. In addition to the amblyopia, nervousness, insomnia, and anorexia, shortness of breath developed, through the fact that this remedy is a cardiac depressant. In cases of arteriosclerosis or valvular trouble, it must be used with great care. The prognosis is, however, favorable, for with its discontinuance improvement goes on and even a return to normal in some cases takes place."

Good results have occasionally been recorded from the use of the thyroid in lupus, scleroderma, ichthyosis, psoriasis, alopecia, etc., prostatic hypertrophy, melancholia and rheumatic affections. It has been tried also in old syphilitic ulcerations, but with little success. Good results are reported from its use in cases of large contracting cicatricial masses, which resemble true keloid.

Stimson reports upon the action of this drug in gynecolgy, and states that he "finds the happiest results from its use in dysmenorrhea and ovarian neuralgia; in some cases of myxedema, and in women deprived of the thyroid gland, in endometritis with hemorrhages, in ovaritis, menorrhagia or metrorrhagia, cancer of the uterus, frequent abortion, uterine fibromata and myomata, in uterine hyperplasia and subinvolution, as a galactagogue, and in chronic ovarian and tubal disease."

Nicholson states that "thyroid extract acts as a specific in favoring metabolism, and believes in its use in puerperal eclampsia," for he "thinks the chief symptoms of this condition are due to thyroid inadequacy." "Thyroid extract," according to him, "is indicated in the preeclamptic state and after the onset of convulsions."

Davies states that "it is indicated in adenomata or cysts of the thyroid."

A tendency to hemorrhages is caused by giving thyroid, consequently the drug is beneficial in amenorrhea and like conditions. The thyroid function is closely related to the menstrual function, thus it is disturbed at the menopause.

Kashiwamura has contributed recently to the study of the thyroid in infectious diseases. These include diphtheria, scarlet fever, miliary tuberculosis, measles, fibrinous pneumonia, puerperal fever, typhoid fever, septicemia, and pulmonary tuberculosis. It was found that in these diseases the connective tissue of the thyroid is increased in amount, especially in diphtheria, typhoid and tuberculosis. In a large number of these cases there is an accumulation of colloid material in the interstitial lymphvessels, but this is not characteristic, as it is also seen in noninfectious processes. The substance of the gland itself is not characteristically changed.

Osborne suggests thyroid as the best alterative and preventive of further connective tissue formation in the sclerosis of organs, as in endarteritis, small, contracted kidney and cirrhosis of the liver.

MacIlwaine reports the case of a mother and daughter, both suffering from myxedema. He thinks it very possibly shows an inherent susceptibility of the thyroid to toxic influences.

Besides its use in myxedema, operative myxedema, cretinism, exophthalmic goiter, and obesity (in which, however, the heart needs careful watching), several cases of cure or improvement have been reported of diabetes mellitus, eczema, and even in hemiplegia. It is claimed also to render more active the process of bone formation, and is, therefore, useful in fractures.

O. T. Osborne states in regard to the dosage of thyroid that in the normal individual small doses would be little noticed for a long period, but that when large doses are given of either thyroid gland, extract, or iodothyrin, for some time there will be nausea and vertigo, with increased cardiac action, a tendency to increased sweating and diuresis, with possibly faintness, cerebral irritation and tremor, and even glycosuria may be produced. He believes that the urine should be carefully examined in cases of diabetes to determine its doing no harm. Otherwise it should not be given in any case when glycosuria exists. In cretinism the dose should be small, as should the dose of all organic extracts whenever administered, as the output of any one of the glands is very small in twenty-four hours. In the case of a child 0.03 gm. (½ gr.) three times a day suffices. If the temperature rises, the pulse grows rapid, or the child becomes nervous, irritable or sleepless, too large a dose is being given and should be diminished. Briefly, if there be cerebral excitement, palpitation and progress in loss of weight, thyroid treatment is contraindicated; if the patient is sleepy, apathetic, with little or no palpitation, no headache and is increasing in weight, thyroid will probably be of benefit.

In the administration of thyroid, the gland itself, raw or very slightly boiled, may be given. A quarter or the half of a sheep's gland constitutes the daily dose. But it is better to use the glycerin extract or the dried and powdered gland, as this is thoroughly efficient. A grain three times a day is the initial dose. This is increased to 15 or 20 grains a day and continued until physiological symptoms appear.

*Thymus gland,* or its extract, has apparently given somewhat similar results to the thyroid, with the exception that it does not stimulate the heart or cause increased metabolism as does the thyroid, and causes, therefore, no loss in weight.

Rushton Parker has used the extract in four cases of exophthalmic goiter. In none of the cases was the course of the disease or the symptoms materially influenced. However, Osborne declares that this treatment is beginning to have a large backing.

*The thymus* contains more nuclein and consequently physiological phosphorus than any other organ in the body. Its function is certainly exercised during early life, as it atrophies and disappears at the time of puberty. Osborne believes that the thymus treatment is often beneficial in hypersecretion of the thyroid. He also gives thymus to all of his tuberculous patients, and it always improves their condition.

Mendel believes that the thymus gland greatly influences the formation of the tissues, especially those of the osseous system during the period of growth. He says that the enlarged spleen may be due to its attempt to substitute for the defective thymus. He thinks that there is some relation between this gland and rachitis. Friedlaben made three hundred autopsies on children, and in each case of rachitis the thymus was greatly altered. During the last five years Mendel has treated more than one hundred rachitic children with thymus. The daily dose was as many grams of the fresh gland as the child was months old. There were no untoward effects in any case. The functional disturbances of the disease were quickly abolished. The abnormal sweating ceased. The attacks of laryngismus stridulus decreased, and the enlarged spleen and dis-

tended abdomen diminished in size. When the treatment was interrupted, the symptoms returned. In many cases the rachitic changes in the bones began to subside. The fontanelles decreased in size and dentition was promoted. The object of this treatment is to substitute the gland extract for the deficient internal secretion, while at the same time the general health is improved. In this manner the gland is gradually restored to its normal condition. If, however, the gland substance is destroyed by congenital syphilis or tuberculosis, this treatment cannot bring about a cure.

The dose of thymus is two or three 3-gr. tablets a day.

*Suprarenal therapy* has recently gained the most enthusiastic followers, and as its literature for the present is rather scattered, a somewhat lengthy review may be in order.

Suprarenal extract increases the tone of all muscular tissue. On this account, and also by its astringent effect upon the blood vessels, it is the strongest known stimulant to the heart and an ideal heart-tonic, although it does not seem to affect the normal heart. Because of this property it is also employed in Addison's disease, but the results in this field up to this time seem to be quite unsatisfactory. One reason for this may be that in many cases the treatment has been begun in too late a stage. It is also employed in diabetes insipidus and other diseases arising from or accompanied by vasomotor disturbances. Its aqueous solution has of late gained a well-earned reputation as a powerful astringent, whether applied locally or taken internally. It is probably the best hemostatic known, as it acts by contracting the small arteries, and has no chemical or other effect on the blood, is nonirritating and does not form a clot, as it does not coagulate; it does not combine with albumin and thus become inert, and as it acts in very dilute solutions, it has no cumulative effect. It relieves acute congestion, for example, in the early stages of inflammation.

Given by mouth in 0.3 gm. (5 gr.) doses, the suprarenal extract will quickly ameliorate congestion of any part of the body, the eye, ear, nose, throat, lungs, liver, kidney, bowels, etc. Floerscheim states that the capsules should be allowed to dissolve in the mouth, since the potency of the drug is diminished by the action of the gastric juice. He employs it in various pulmonary diseases and suggests its use as a general vascular tonic.

Solis-Cohen declares that suprarenal extract is not a specific for asthma, and is not indicated in those cases which are truly spasmodic, depending upon the contraction of the bronchial muscle. But it is valuable in those cases depending upon congenital defect of structure or of metabolism, by which the vasomotor system is affected.

Only one function of the suprarenal gland is established without doubt, that is the maintenance of vascular tension.

Hemorrhage from the nose or gums can be stopped even in hemophilia by the liberal application of the aqueous extract or emulsion. Myles does almost bloodless operations on "bleeders," and Otis has controlled hemorrhage from the bladder by the same means.

Moore has used it in diseases of the urethra successfully. It gives great relief in cases of gonorrhea with burning urination.

Meara has had great success with this drug in the treatment of pruritus of the vulva and anus.

Brunet reports cases of severe neurasthenia successfully treated with the extract. He also used it in gastrointestinal hemorrhage.

Peters thinks it relieves the pain of some ulcerating cancers, and may replace morphin, while Davies uses it to relieve pain in cancer of the breast, esophagus (local), and tuberculous laryngitis.

The extract is now largely superseded by the active principle adrenalin hydrochlorid. This is offered in a clear solution, and is used in congested membranes, though these will bleed sometimes when cut. It is useful in nasal catarrh, but it does not shrink polypi. Is used in shock and from narcotic poisons, as well as in anesthesia narcosis.

Crofton believes that there is a powerful diastatic ferment in the suprarenal gland, nearly as great in quantity as is found in the pancreas.

On account of its hemostatic and astringent action suprarenal extract is serviceable in eye, nose and throat work.

When applied locally as an aqueous extract, to the nose or throat, it whitens the inflamed mucous membrane in one minute, and is an adjuvant to cocain to secure anesthesia. Together with cocain in cases of superficial ocular surgery it is valuable in those patients in whom ether and chloroform are contraindicated.

Suprarenal extract given internally in 0.3 gm. (5 gr.) doses, reduces in a few minutes the turgescence of the turbinated bodies. It is thus valuable in epistaxis. Somers speaks of the possible danger of sepsis in its application in cases of epistaxis, and advises the addition of 1 gr. of carbolic acid to 1 dram of sterilized water containing 10 gr. of suprarenal extract. When this is filtered it is permanent and sterile.

Suprarenal extract is regarded as useful by some in hay-fever, both in local and general administration. Its effect in these cases, however, soon subsides, but if the application is renewed every two hours or more the condition sometimes permanently improves. Nasal hydrorrhea has been relieved by its use. It has been suggested that suprarenal may cause secondary hemorrhage, or an erectile condition of the nose which will surpass the original condition of a fresh coryza. Hopkins believes that after its use in nasal operations, intranasal packing is advisable on account of the danger of secondary hemorrhage. Tonsilitis is temporarily relieved by the local use of suprarenal extract, and even its internal administration often causes relief. Swain has great confidence in its use in quinsy. He sprays the throat with the extract and then applies cocain. The swelling subsides so that the patient is enabled to swallow a little milk, or very soft food, which before the treatment was utterly impossible. Boeker, in a case of acute edema of the throat, believes that this remedy saved a life. Solis-Cohen had the same favorable experience in treating a case of angioneurotic edema of the pharynx and tongue.

Clement Bloch reports edema of the soft palate and uvula, congestion of both tonsils and lateral pharyngeal columns, followed by superficial ulcers of the tonsils, after the use of suprarenal extract dusted into the nose. He attributes the edema and ulceration to the strong vasomotor action of the gland which produced venous stagnation.

Bates says that this remedy is most useful for the relief of deafness. Acute cases are permanently relieved in one treatment, and chronic ones are temporarily benefited. In the latter the internal use of five grains three times daily is often very useful. Curtis has had success in the treatment of acute laryngitis of singers whose vocal cords were congested or relaxed. Carpenter has used it in dental practice to reduce hemorrhage and swelling of the gums and to produce anemia. He finds it advantageous in fitting bands for crowns, adjusting cervical clamps, excising fungous growths and in pyorrhea

pockets. Somers recommends it in 5-grain tablets for the embarrassed respiration of peritonsillar abscess.

Suprarenal extract lessens the congestion of purulent inflammations of the conjunctiva and is on this account very serviceable in scleritis, conjunctivitis, keratitis, and even iritis. Many operations on the eye are made bloodless by its proper employment.

By reducing the congestion of the mucous membrane it is often very beneficial in tinnitus, caused by partial occlusion of the eustachian tube, and for the same reason also applicable in acute and chronic catarrhal otitis media. A case is reported in which the hearing was improved to the extent of several inches after two drops of adrenalin solution was applied. It was combined with other treatment, so how much was due to the adrenalin alone is doubtful.

Hill finds that it at least improves the mental condition in epileptics. He used it internally in combination with calcium chlorid and small doses of sodium bromid.

Crary has reported its use in exophthalmic goiter with improvement of cardiac action, tremor, general strength and disappearance of the goiter.

Bates reports on its effects in diseases of the heart. An intermittent pulse becomes regular; a weak pulse becomes stronger; the strengthened heartbeat equalizes the circulation, and consequently the circulation to all parts of the body, and so anemia, or hyperanemia, is replaced by a normal condition. Unfortunately, the action of this drug is but temporary in such cases.

Floersheim reports excellent effect from its use in mitral regurgitation, but states that it has little effect on aortic disease.

Kenworthy has had success with the remedy in cases of hemoptysis which had resisted all other treatment.

Schafer considers this the most efficient uterine contractor, whether in a pregnant or nonpregnant uterus, and whether applied directly to the muscular tissue or introduced into the circulation. Its value may be enhanced by the addition of calcium chlorid.

Stöltzner reports seventy-six cases of rachitis treated most successfully with suprarenal extract. In cases complicated with syphilis, intestinal catarrh, bronchitis, and pneumonia, an improvement by this method of treatment was never observed.

Postle reports benefit in a case of measles from the internal administration of suprarenal gland.

Holt reports a case of hemorrhage in the newborn successfully treated with the extract.

L. L. Skelton reports a case of Addison's disease in which suprarenal extract failed to afford relief. It did no more toward benefiting the case than did strychnia, digitalis or ergot.

As a preservative for suprarenal gland solutions, Seymour Oppenheimer has found that an almost permanent solution may be made by adding one dram of the dried suprarenal to an ounce of a one per cent. solution of resorcin.

*Pituitary body* has been applied with good results in acromegaly, and Dana claims some benefit from its use in paralysis agitans. Osborne believes that there is undoubtedly a relation between the thyroid gland and the pituitary body, as disturbance of one of these glands seems always to be associated with disturbance of the other. The pituitary is always diseased in acromegaly. There are also symptoms due to perverted secretion of the thyroid. He believes in the hypersecretion theory, and is convinced that giantism is due to hypersecretion of the hypophysis, while acromegaly is due to a disturbed or diminished secretion. It is quite probable that in certain stages of acromegaly too much physiological phosphorus, which is possibly formed by the pituitary, is retained in the body Moraczewski states that there is a tendency in acromegaly to retain in the system the chlorids, calcium, phosphorus, and nitrogen—the tissue-building substances. The one established use of pituitary substance is in the condition of acromegaly, when the toxic headaches are much relieved by pituitary substance.

*Spleen extract* is employed in Hodgkin's disease, leucocythemia, anemias, chlorosis, and all diseases with enlarged spleen; in exopthalmic goiter, and in enteric fever some good results have been noted. It seems to be beneficial in the treatment of exophthalmic goiter, though it has an irritating effect on the stomach. Carpenter contributes an enthusiastic article on this subject, wherein he claims that when given in doses of 0.3 gm. (5 gr.) three times a day it will reduce the temperature of typhoid fever without undue diaphoresis; besides it improves the symptoms and restores the patient to a normal condition both steadily and quickly.

Jez has prepared an extract made from the spleen, thymus, bone-marrow, brain and spinal cord of animals which he has immunized against *typhoid fever*. He has administered this remedy to typhoid patients, and concludes that it has a specific therapeutic effect in this disease. It had no injurious effects; besides, it assists in making a differential diagnosis. He states that its use shortens the duration of the fever, and in fact is attended by the most encouraging results.

*Hepatic extract*, as used by Gilbert and Carnot in a case of diabetes mellitus, due to functional debility of the liver, reduced the sugar in the urine. It is said to be beneficial in alcoholic cirrhosis.

Schober and Mallett have suggested the use of *parotid gland* for the pains of dysmenorrhea. Osborne reports a case of epilepsy in which he used this substance with the most astonishing results. The attacks ceased and have not recurred for over a year. It controls pain in simple ovaritis.

*Pepsin* as a commercial product, is in general derived from the gastric glands of the pig. There is a variety, however—ostrich pepsin used in Argentina, which is made from the gizzard of the ostrich. This extract is made in great quantities. The results from its use have proved to be variable. It is supposed to be a valuable aid in the digestion of albuminous food.

*Extract of pancreas* is used for "peptonizing" or predigesting food. It is made from the sweetbreads of animals. The medium in which it acts may be either acid or alkalin, contrary to the idea that it will not act in the stomach or in an acid medium. The longer peptonization is allowed to go on, the more bitter the product will become. In order to avoid this disadvantage it is often well to administer the pancreatic extract with the food. It is very valuable, especially in summer, in feeding invalids and infants. Its effects are variable in cases of diabetes mellitus. Von Noorden found that it gave good results in chronic steatorrhea accompanying diabetes.

*Renal extract* was of temporary benefit in nephritis and uremia.

*Pulmonary extract* was favorable in pleuro-pulmonary suppuration with osteoarthritis. The progress of the bony deformities was arrested.

*Nerve extracts* have been recommended in epilepsy, locomotor ataxia, chorea and neurasthenia.

*Testicular extract* or orchitic fluid has been the subject of more praise and condemnation than all the other animal extracts, since Brown-Séquard first heralded its praise as the very fountain of youth. It

is rich in nuclein and phosphorus, and as such is a good stimulant. Its action as a nerve tonic and aphrodisiac cannot be denied, though we may not recognize the claims made therefor in the treatment of neurasthenia, epilepsy, locomotor ataxia, etc. Professors Poehl and Senator have established beyond dispute that a properly made extract of the testicle (such as the hydrochloride) has a powerful antilaxic effect by reducing an abnormally diminished alkalinity of the blood to its normal state. By aiding metabolism and preserving the organism from autointoxication, its many champions also claim excellent results in many conditions from such causes as diabetes, mellitus, uric acid diathesis, rachitis, neuroses, tabes, syphilis, pneumonia, typhoid fever. In carbon dioxide poisoning or that from chloroform anesthesia, where the oxidizing power of the blood is reduced, this substance is claimed to restore the blood to its normal state. The elaborate and very fetching theories in this line are, however, though very interesting, too lengthy for this review. Thelberg gives the following statement of Poehl's views: It is said to induce quiet and refreshing sleep. Its influence on the sexual system is not specific, but is said to depend upon its general tonic effect. Finkelstein and others state that it should not be given with mineral acids nor with potassium bromide. It is also contraindicated in maniacal cases with sudden outbursts of excitement and in some forms of epilepsy.

*Prostate gland* extracts have been employed in hypertrophic changes of the prostate.

*Mammary extract* has been tried in the debility of women, in uterine hemorrhage and in menstrual backache, as well as in uterine fibroids, but its value is as yet experimental. Shober, however, has used it in uterine fibroids with good results. It has controlled bleeding, and inhibited the growth to a certain extent, and it makes the patient more suitable for operation.

*Ovarian extract* has been used to ameliorate the distressing nervous and vasomotor disturbances coincident with the menopause and after extirpation of the ovaries. Beneficial effect has also been claimed for its employment in chlorosis, in emenorrhea, in symptoms following oöphorectomy, and in amenorrhea from prolonged lactation and hysteria. Ferre and Beston say that an overdose may cause death. In the male it acts as an aphrodisiac. Subcutaneous injections are recommended by Vidal for neurasthenia without any genital affection. Six injections of 3-5 c.c have been said to cure the condition. Uterine hemorrhage has been said to be cured by its continuous use. Its therapeutic value is still unknown. The effects of the removal of the ovaries in cases of cancer of the breast are still experimental. Dorland states that the removal of the ovaries in cases of inoperable cancer—if these organs are active—often results in the arrest of the progress of the disease or even in the destruction of the neoplasm. The results are better if as much as possible of the growth is excised and thyroid extract be given in full doses—10 to 15 grains daily. This treatment is not so favorable in older women.

*Brain extracts* have their ardent advocates, who offer most attractive theories. Althaus suggests, for example, that their action is due, first to the injection of a highly specialized pabulum of nervous matter; second, to the decomposition of its lecithin protagon through the alkaline blood whereby not only glycerophosphoric acid, but also cholin, are formed. He claims that cholin, by its oxidizing action on the blood acts as an antitoxin. Cerebrin is highly recommended by Lion of Russia as a remedy in epilepsy. He advises the administration of from 5 to 10 grains daily. Besides this, the author employs the "bromide-diet," which consists in the withdrawal of sodium chloride and meat, and, instead, giving as a daily diet, milk, eggs, bread, gruel, potatoes, butter, sweetened tea, cider and three grains of bromide. The physical manifestations are quickly subdued. Dangerous patients become mild in disposition by means of this treatment. The method of treatment, that is, its duration, size of dose, etc., will have to be determined by further work in this line, as well as the real value of the treatment.

*Bone marrow extracts* have lately, and seemingly with good cause, become very popular in the treatment of both primary and secondary anemias. Various firms have prepared either extracts of the red marrow *per se*, or combinations of this extract with nucleo-albumins of iron which certainly are both rational and clinically successful. The near future will without doubt give further light on this subject. The extract is generally prepared by soaking the broken ribs of young animals in glycerin for three or four days. The glycerin is then strained and is ready to use. The dose is from one to three ounces each day.

## THE HYPODERMIC USE OF THE SALICYLATE OF MERCURY IN THE TREATMENT OF SYPHILIS.

By EDWARD F. KILBANE, M.D.,
NEW YORK.

ASSISTANT SURGEON ROOSEVELT HOSPITAL O.P.D., INSTRUCTOR IN ELECTRO-THERAPEUTICS, N. Y. POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

To formulate a method of treatment by the use of one drug that would or could be applicable to every case of syphilis is out of the question, because of the unlimited manifestations of the disease and the many indications for treatment presented.

Taking for granted, however, that mercury in some form is indicated, we have, I believe, in the intramuscular injection of the salicylate of mercury a mode of administration that is free from most, if not all, of the difficulties encountered in the use of the drug when administered in the ordinary ways (mouth, inunction, vaporization, etc.), in that it is cleanly, safe, efficient, entirely practical for office or dispensary use, easy of administration, and capable of accurate dosage. It is entitled to consideration and trial as the routine treatment or foundation of treatment, to which may be added, or for which may be substituted, other treatment when required by special indications or conditions. It is equally well adapted to the modified expectant, the interrupted or the continuous method of treatment.

The objections that are usually offered to its general use, are that it is irksome to both the physician and the patient, painful to the latter, that there are ever present the dangers of embolism and fatal mercurial poisoning, and that the treatments are likely to be followed by the formation of abscesses and painful nodes of the site of the injections. These objections are groundless, for the observance of a few simple rules will prevent any of the accidents from happening.

By having the needle and syringe prepared as I shall afterwards describe, each treatment can be completed in five minutes. Dispensary patients can be treated in even less time. At the most, one treatment a week is enough for the usual run of cases. Surely this is less irksome to the patient than inunction daily for weeks at a time or medication three or more times a day, the latter necessitating the carrying about of the medicine and involving the

danger of detection. In addition, the patient is under the immediate and continual observation of his physician.

Embolism is avoided if the precaution of noting that the needle has not entered a vein is observed. Mercurial poisoning is ever liable in persons exhibiting idiosyncrasy, but fatal results are avoided in this as in other methods of administering mercury if we begin with small doses and gradually increase. Abscess formation is prevented by the aseptic precautions that should be observed before every hypodermic injection. If the proper technique is followed, painful nodes will not occur, except possibly after the first few injections.

The essential point in the successful treatment of syphilis is to get into the circulation the maximum quantity of mercury that the system will tolerate without ill effects. Leaving out of consideration the patients who are careless of or who neglect their treatment, the obstacles usually encountered are the local irritating effects of the mercury on the skin and the gastrointestinal tract, and these effects are almost surely avoided by the judicious hypodermic use of the salicylate. How often we see cases of syphilis as ordinarily treated, in which the symptoms are progressing but in which we are compelled to discontinue treatment because of the severe local effects of the mercury. Sometimes we can of course, by the use of other agents, control or lessen the local effects of the mercury until the constitutional effect is secured.

In these cases when treated by mouth we may know how much mercury is taken by the patient, but do we know how much is absorbed and how much is excreted unchanged? Of the absorption from inunction we know even less. We can only know that the patient is getting enough specific medication when we see that he is getting too much. In other words, we have to give too much mercury and thereby produce unpleasant effects, before we are sure that the patient is getting enough. If we use the salicylate of mercury hypodermically, we can regulate the dose without one-tenth of a grain, and we have practically no unpleasant local effects and only very exceptionally do we see any effect at all on the alimentary canal.

The technique that follows is that used in the clinic of Dr. Walter C. Klotz, at the Roosevelt Hospital O. P. D., and the recorded cases are from the same clinic.

The salicylate of mercury is suspended in liquid albolene 48 grains to the ounce, thus making a 10 per cent. preparation. For dispensary use this is put up in ounce quantities and sterilized.

The dose to begin with is usually ¾ of a grain. The interval between treatments, 4 days. The dose and the length of the intervals between the treatments are gradually increased until the patient is taking one and one-half grains weekly. The full dose of the 10 per cent. preparation is therefore 15 minims. If the patient has been taking mercury in some other manner, a larger dose may be used at the start. In some cases a dose larger than a grain and a half may be used to combat special symptoms, but in these cases the more frequent use of a soluble salt of mercury will probably give better results. Potassium iodide can be administered by mouth at the same time.

An ordinary hyperdermic syringe does very well, but any of the syringes designed especially for this purpose may be used. The needle should be at least one and a quarter inches in length, and of about 18 caliber. Needles of smaller caliber are impracticable, because the mercury will clog in them. It is essential that the needle be very sharp. At the dispensary we sharpen the needle on an oil stone frequently. When the needles wear too dull to admit of this sharpening they are returned to an instrument maker and resharpened at little cost. By getting needles that are originally about one and five-eighths of an inch in length a long life is assured them.

When not in use the syringe is immersed in an antiseptic solution. The needle is sterilized by boiling. In objecting to the hypodermic mode of treating syphilis one of the arguments used is that it is necessary for the physician to prepare his hands as for a major operation. This is not at all necessary. If the needle after sterilization is handled with a pair of sterile forceps and not allowed to come in contact with anything not sterile, perfect asepsis is maintained, as the hands need not come in contact, either directly or indirectly, with the needle or the site of injection. In private practice I have found it advisable to sterilize the needle immediately after use, and then keep needle, syringe, and forceps for handling, in an alkaline strongly antiseptic solution ready for immediate use when required.

The gluteal region is the usual site of injection, alternating from side to side. The muscles of the back or of the calf of the leg may be used if desired. The buttock is cleaned as is usual for a hypodermic injection. The patient's leg is placed so as to relax the gluteal muscles, and he is instructed not to jump when the injection is made. The syringe is filled with mercury, the needle is attached, and air bubbles are excluded. The needle is entered firmly and quickly into the muscles as far as the guard, care being taken to avoid injuring the periosteum. The relations of the anatomical structures in the vicinity should, of course, be borne in mind. The mercury is then driven very slowly and gently into the muscles, the needle quickly withdrawn, and the part massaged with a vigorous rotary motion for one minute. This massage prevents any hemorrhage from the puncture hole and lessens very materially the probability of any soreness or lameness following.

During the past year we have treated sixty-four patients by this method. A total of four hundred and ten treatments have been given, and we have never had an untoward result of the injections. At first this method was used only in selected cases when it was desired to get the patient quickly under the influence of mercury. Gradually its use was extended, until it is now employed in all new cases in which mercury is indicated. The results have been very satisfactory.

In this series of sixty-four cases thirty-three patients received between 1 and 5 injections, twenty-one patients received between 5 and 10 injections, ten patients received between 10 and 25 injections. Of these cases thirty-six received mercury in some other manner, either before or after the injections. Twenty-eight received hypodermic medication exclusively. Four patients discontinued treatment because of removal to out-of-town places. Nine patients came to the clinic not more than twice. This is about in accordance with the usual run of this class of patients, many coming to the clinic only for a diagnosis, and as soon as that is made they place themselves under the care of a private physician. In addition to these nine, twenty-seven patients discontinued attendance while under hypodermic treatment, but of these only five had any subjective symptoms of syphilis at the time of their last visit. We have at the present time twenty-three patients under active treatment by this method. In but two cases was it necessary to discontinue the injections. One patient complained so bitterly of the pain after

the first injection that it was not repeated. One patient complained after the first injection; treatment was discontinued for a while and later recommenced; this patient has since had eight treatments without any inconvenience. One patient requested the discontinuance of the injections after eight treatments. This is the only case in which complaint was made after any but the first few injections.

From observation I can say that in both secondary and tertiary cases the symptoms disappear more quickly under this than under any other treatment. Actual figures, however, I cannot at this time give because of the necessary brevity of the dispensary histories. At some future time I hope to be able to give more accurate data on this point.

As soon as a positive diagnosis is made, the patient is acquainted with the nature of the disease, the precautions necessary to prevent infection of others, and the hygienic adjuvants of treatment, and he is impressed with the necessity of continuing treatment, even in the absence of symptoms for a period of years.

This mode of treatment is then explained to him, its advantages are pointed out, and he is assured that it is practically painless. He is told that he will suffer some—possibly considerable—discomfort after the first treatment, that for from twenty-four to forty-eight hours after the injection he will feel as if he had been kicked and that he may be a little lame. but these symptoms are less after each treatment until, in a very short time, he will suffer no inconvenience, either at the time of or following the injections. He is requested to tell if he is caused more inconvenience than he cares to stand, and he is promised that the treatment will be changed as soon as he complains. As a rule the patients are willing to begin the treatment. If they have previously taken mercury by mouth they know personally of the disadvantages and drawbacks, and gladly consent to the change.

When they return for the second treatment they are apt to complain of the dull ache and pain following the first injection. They are again told that the second injection will cause much less discomfort than the first, and that the future ones will cause none at all, and they are advised to continue the treatment for a short time longer at least.

By giving a little attention to this point, we have been able to get the patient's cooperation in almost every case, for it is a fact that except after the first few injections there is no pain or discomfort connected with the injections, and the patients offer no objection whatever to continuing the treatments. After the first few treatments they will continue of their own accord. Patients who have had treatment both by mouth and needle and return to the clinic after an absence, invariably request that the latter method be used.

In conclusion, I want to recommend this treatment for trial in every case of syphilis in which the administration of mercury is indicated for a period of time. It possesses many advantages over the methods in vogue, and has but few and slight disadvantages when carefully employed.

24 West Sixtieth Street.

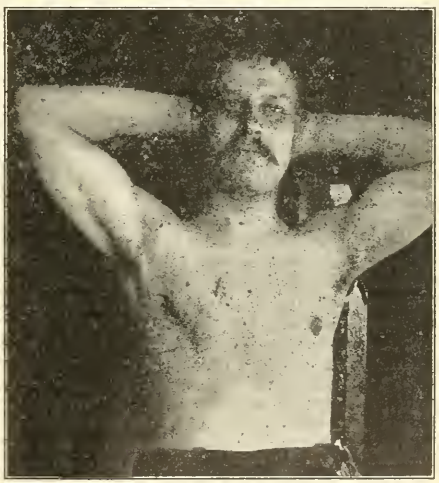
---

**Disinfecting the Confessional.**—On the advice of the Mexican Board of Health, the government has issued an order for the daily disinfection of confessionals in all the churches of the capital. Priests neglecting the order are subject to fine and imprisonment. According to the health board, the confessional may be an active means of spreading contagious and infectious diseases, and its purification is important in controlling epidemics

## CARCINOMA OF THE MALE BREAST CURED BY THE RÖNTGEN RAY.*

By SINCLAIR TOUSEY, A.M., M.D.,
NEW YORK.
SURGEON TO ST. BARTHOLOMEW'S CLINIC.

This patient, Albert D., is a strong, well-developed man of 33 years, a ribbon weaver, married and with nothing in his family history to account for malignant disease. Although he was not conscious of pressing his breast against the apparatus at which he works it seems probable that this was the case. About December, 1901, he noticed a hard swelling of the right breast, which increased in size until its removal by myself in November, 1902. The operation consisted in an elliptical excision of the breast, and a plastic operation for covering the defect. No involvement of the axillary glands was present and they were not removed. The tumor presented the gross appearance of a fibroma, but the pathological examination showed it to be malignant. The following is the report of Dr. E. E. Smith: "The specimen consists of the nipple and skin for a radius of



two inches, together wih the underlying subcutaneous fat, gland, and connective tissues which are invaded with a hard growth involving the central portion of the entire specimen. The gross appearance is suggestive of fibroma. Sections have been cut from various portions and show a dense fibrous structure with only here and there cellular elements which, however, characterize the specimen as carcinomatous." In May, 1903, the man returned to St. Bartholomew's Clinic with a tumor of the left breast, which was somewhat softer and not so adherent to subjacent parts, but was more tender than the other. *X*-ray treatment was adopted, and after five months the tenderness disappeared. It was seven months before the tumor began to diminish in size, and it entirely disappeared after eleven months' treatment. There is now no sign of recurrence, although he has had no treatment for 13 months. The application had been of such a strength as to keep the skin constantly somewhat reddened, and with a scaly desquamation. But at no time was this reaction sufficient to produce swelling or vesication or tendency to ulceration.

*Case shown at a meeting of the Surgical Section of the New York Academy of Medicine May 5, 1905.

The tube was nearest the affected breast, but the rays were allowed to reach the entire front of the chest and the axillæ. An eight-inch induction coil was used with a Caldwell interrupter, and a primary current of five amperes. The tube was a light anticathode, 35 centimeter Gundelach tube with a medium vacuum (about 2½-inch resistance and 5 radiometer) and the anticathode was at a distance of nine inches from the skin. The exposures were for about nine minutes; for the first five months once a week, and after that twice a week.

The case is typical of a class of cases in which the greatest degree of malignancy has not yet developed, and no metastases have occurred. Such cases I believe are sometimes susceptible of cure by the *x*-ray.

63 West Fifty-sixth Street.

## REMARKS ON THE PRESENTATION OF A PORTRAIT OF DR. ANDREW HEERMANCE SMITH.*

By GEORGE L. PEABODY, M.D.,

NEW YORK.

*Mr. President and Fellows of the Academy:*

In a charming book, by Schaler, professor of geology in Harvard University, which he calls "The Individual: A Study of Life and Death"—a book which I can cordially commend to you all—the author speaks very thoughtfully and very sanely upon the attitude of man toward death. In the course of an analysis of the very general fear of death which is common to nearly all of us, he comes to consider the dread of being forgotten as one of the usual causes of our fear. It is certainly a very common feeling in man to be somewhat resentful of the brief duration of our fame after we die.

It is a little surprising how complete an oblivion awaits the average of us. To quote Shaler on this point, let me read you the following:

"This vanishing of men, even when they were persons of no small importance, was forced upon my attention by an instance which illustrates the point in a striking manner. About thirty years ago, while looking up the history of New England earthquakes, by chance I made the acquaintance of John Winthrop, Hollisan professor of mathematics and astronomy in Harvard University in the eighteenth century. I found at once that he was a man of power, who had played a large part in his time; that he had really founded the science of seismology in that he had first applied computative methods to the observation of earthquakes; that he had made excellent observations on the transit of Venus while on what was, perhaps, the first scientific expedition in this country; that he was a Fellow of the Royal Society and a member of the Governor's Council, the latter in those days an index of station of no mean sort. Furthermore, that from his lectures probably came the movement which led to the development of the interest of Count Rumford and Benjamin Franklin in physical science. Chagrined at never having heard of this master, I sought at once to see how singular my ignorance was. I inquired in succession of one hundred well-informed persons, including all the members of the then faculty of Harvard College, and found but three who had any recollection of the name. Yet in the society of a college town there is a greater likelihood of traditions being preserved than in the ordinary associations of men."

*Presented to the New York Academy of Medicine, May 18, 1905.

Nature's methods are the best in this as in most of the other relations of life, of which we doctors, sooner or later, come to regard death and oblivion as merely a part. Those who come after us will have their own lives to lead, their own duties to perform, and only their own finite means to apply to all their ends. If we had the power arbitrarily to enforce upon them a memory of ourselves and a familiarity with our lives and our actions, think what a harm we should do them, and through them to all the after-coming race if we were to exercise this power. We should of necessity compel them to omit from their memories facts of far more importance to them to make place for us and our petty concerns.

But I cannot believe that it is well that every individual of every age should be forgotten, or even that only those of very unusual importance, such as victorious soldiers, should be allowed to survive. As that friend of all of us, collectively and individually, Jacobi, has so well said, fame should occasionally fall to the lot of him who saves human life and alleviates human suffering, as well as to him whose highest aim is to destroy life.

It is an inspiration to the present, as it will surely be to the future, in every association such as this Academy, to keep before it the memory of those who have done most to foster its ideals and to advance its welfare. Not only are we helped in our daily routine of duty by a knowledge of the way in which they wrought, but theirs are the footprints in the sands of time, which bid us to be hopeful in our hours of darkness, and to take courage in our efforts to emulate them. The ideals and welfare of the Academy of Medicine are worthy objects of a life's devotion; and we are all rendered better members and stimulated in the performance of our duties to our fellow men by hallowed memories of those whose portraits hang upon these walls.

It is strange how enduring the perishable canvas becomes when once we value it for the worth either of the artist or of the man whom it brings back to us. There are paintings in this country, as there are many more in Europe, hundreds or thousands of years old whose many early abiding places have crumbled to forgotten dust as the centuries have passed, and have left them still as beautiful memorials to us and to those who shall follow us.

Books, too, are far more lasting than are the buildings which may chance to house them. There are many valued volumes upon our shelves which have long outlived the many previous homes that have given them passing shelter.

Dr. Andrew Heermance Smith will survive by the writings that he has given to us; and I conceive it to be a pious duty, as it is a pleasure of friendship to present to the Academy this, his portrait, which I do on behalf of his friends.

---

**Tuberculosis Among Negroes.**—Miss Lilian Brandt says that the negro death rate from consumption, which before the civil war was less than that of the whites, has increased with such rapidity that it now is about three and one-half times greater than the latter. The following figures show the death rate from consumption between the ages of fifteen and forty-four for every 100,000 persons in 1900:

Negroes in United States, 584; Ireland, 428; Bohemia, 235; Scandinavia, 234; France, 221; Germany, 206; Scotland, 201; Canada, 200; United States—native-born whites, 163; England, 151; Italy, 150; Russia, 131; Hungary, 113; Poland, 67.

# MEDICAL RECORD.

*A Weekly Journal of Medicine and Surgery.*

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, July 29, 1905.

## THE PANAMA CANAL AS A MEDICAL PROBLEM.

THE dependence of great interests upon the advice and work of members of the medical profession has never, perhaps, been more forcibly brought home to the people at large than in the present question of constructing the Panama Canal. The engineering and administrative problems involved are without doubt of immense magnitude, but at present they must take second place in point of practical importance as compared with the task of rendering the Canal Zone habitable for the working forces. It was not technical difficulties that baffled the genius of De Lesseps in his attempt to unite the oceans, but financial mismanagement at home and disease on the Isthmus. The former element presumably need not enter into our calculations, but the work of sanitation still remains as a necessary preliminary to the task of excavation. Medical knowledge, particularly of tropical diseases, has made great advances during recent years, and the experience gained in the sanitation of Cuba will prove invaluable; but one of the notoriously most insalubrious regions of the globe cannot be rendered healthful in a short space of time, nor such diseases as yellow fever, beriberi, malaria, and dysentery be snuffed out like the flame of a candle. Progress with the work on the canal is not therefore to be gauged by the number of cubic yards of rock and soil removed, but by the statistics furnished in the health reports. These show that the labors of Col. Gorgas and his aides have met with most satisfactory results, in spite of the croakings of the sinecure hunters who keep returning from the Isthmus disappointed and shorn of their golden hopes.

This fact was emphasized by President Roosevelt in his address to the Associated Physicians of Long Island on July 12, at Oyster Bay, in which, after commending the work accomplished, he said that the alarmist reports which have lately been coming from the Isthmus might safely be disregarded, as they emanated almost entirely from people who were anxious to justify their defection from the spot where work was to be done by painting the local conditions in as lurid colors as possible. It was more than likely, he continued, that from time to time there would be troubles as regards sanitation, just as there would be difficulties in the engineering and administrative departments, and that such difficulties would encourage a large number of excellent but timid persons to express dire forebodings as to the outcome, and to fear that the whole thing would be a failure. It would not be a failure, however, but would be a success, because every check would be treated not as a reason for discouragement or for abandoning the work, but as an indication of the direction in which improvements and modifications in plans were necessary in order to avoid a recurrence of just that particular difficulty. What was being done in Panama was but a sample of the things that this country has done during the last few years, and in which the medical profession has borne so prominent a part.

## FISH AS FOOD.

THE question of fish as food is a very wide one, viewed from whatever standpoint. By a few the value of fish as a nutritive agent is exaggerated, while some go to the other extreme and declare that fish as an article of food possesses no especial nutritive qualities. As usual, the truth lies in the happy mean, and fish, although not necessary to the preservation of good health, yet holds quite an important place in a diet table.

The U. S. Department of Agriculture has issued recently Farmers' Bulletin No. 85, written by C. F. Langworthy, Ph.D., which considers fish as food from all aspects. It is shown that the market value of fish is affected by various conditions. Among these are the locality from which they come, the season in which they are taken, and the food on which they have grown. "In general," says Dr. Langworthy, "it may be said that fish from clear, cold, or deep water are regarded as preferable to those from shallow or warm water, while fish taken in waters with a rocky or sandy bottom are preferable to those from water with a muddy bottom."

As to the preservation of fish, it is stated on good authority that in commercial practice 25° F. is regarded as the proper temperature for storing fish which has been previously frozen. For dried fish the proper temperature is 25° F., for fresh fish 25° to 30°, for oysters 33° to 40°, for oysters in the shell 40°, and for oysters in the tub 35°. Oysters should not be frozen. With regard to the nutritive value of fish the author treats the subject at considerable length, and supplies comparative tables in which is shown the nutritive value of all kinds of edible fish, of other animal foods, and of vegetable foods. Fish is like meat, essentially a nitrogenous food, although oysters and other shell fish contain some carbohydrates. So far as cost is concerned fish compares with the cheaper meats, and the cereals are the least expensive sources of protein. Referring to the digestibility of fish Dr. Langworthy states that experiments have demonstrated that fish and lean beef are about equally digestible. In each case about 95 per cent. of the total dry matter, 97 per cent. of the protein, and over 90 per cent. of the fat were retained by the body. Other experiments of the same character indicated that salt fish is less thoroughly digested than fresh fish. As with meat the leaner kinds of fish, such as cod, haddock, perch, pike, etc., are more easily digested than the fatter kinds, as salmon, shad, and mackerel. The information with respect to the digestibility of shell fish is scanty. It is, however, of general belief that oysters belong to the more easily digestible class of foods.

The writer places the chief uses of fish as food (1) to furnish an economical source of nitrogenous nutrients, and (2) to supply the demand for variety in the diet, which increases with the advance of civilization. The old theory of early writers that fish con-

tains large quantities of phosphorus, and is, therefore, particularly valuable as brain food, has no foundation in fact. The percentage of phosphorus in specimens thus far analyzed has been no larger than is found in the flesh of other animals used for food. But even if such were the case, there is no proof that phosphorus is valuable as a brain nourisher. Physiologists declare that phosphorus is no more essential to the brain than nitrogen, potassium, or any other element which occurs in the tissues. Nevertheless, physiologists particularly recommend fish as a desirable food for persons of sedentary habits, because it seems to be less "hearty." As Langworthy points out, although such statements do not depend upon experimental evidence, they are thought to embody the result of experience.

As regards the possible dangers from eating fish, the author draws attention to the fact that fish may contain parasites, some of which are injurious to man, which, however, are destroyed by thorough cooking. Ptomain poisoning usually occurs when putrefaction of the food is present, so that great care should be taken to eat fish only when it is in perfectly good condition. It is said that there is an act of Parliament, passed in 1698, which has never been repealed, permitting the sale of mackerel an Sunday except during the hours of divine service. The frequent occurrence of poisoning from the eating of stale fish which had been caught on Saturday, and not sold until Monday, was the cause of the enactment of this permissive law. Fish which has been frozen is especially likely to contain injurious ptomains. Canned fish should never be allowed to remain long in the can after opening, but should be used at once. It goes without saying, that oyster beds should be free from sewage pollution, and oysters when "floated" or "fattened" should never be placed in water contaminated by sewage.

## WORK AS A THERAPEUTIC MEASURE.

It would seem from observation, as well as from current medical literature, that the medical profession was growing to look with more and more favor upon the benefits of therapeutic measures other than drugs in the treatment of certain diseased conditions. Electrotherapy, hydrotherapy, phototherapy, psychotherapy, mechanotherapy, heat and cold, rest and diet, with numerous other measures are practised, one or more, in a great variety of disturbances, and with signal success in many instances. Hydrotherapy was laughed at a few years ago; the application of electricity was formerly in the hands of totally incompetent and uneducated men, but now we have the study of these remedial agents as a part of the curriculum in leading institutions of medical learning throughout the country. Weir Mitchell has established the rest cure for neurasthenics; the influences of diet have been carefully studied and applied to disordered conditions; establishments have been instituted where hydrotherapy and electrotherapy may be used in properly indicated cases by those who thoroughly understand their application to diseases. Finsen has proven the great benefit of light treatment in conditions hitherto thought to be incurable. Gymnasia are found in all centers, where the benefit of mechanotherapy has been demonstrated.

A potent factor, that of work, in reestablishing health, mental and physical, has, however, as yet not received the attention and study that it deserves, for without doubt work is the greatest factor in the maintenance of health. Work does not, in the present discussion, mean physical labor alone, for the mind must be employed at the same time in order to secure the best results. Congenial work with mind and hands should be encouraged in all persons, for its prophylactic as well as its curative influences. Rest will prove serviceable doubtless in numbers of cases, but its application should be restricted and carefully studied. There are many conditions where absolute rest will not only prove useless, but really harmful. To send a man from an active business life to one of complete inactivity will often prove disastrous, as much so as to proscribe all food for the obese. Another mistake is arbitrarily to prescribe the character of work for which the patient may have no liking, and which he is incapable of accomplishing. Such work cannot be cheerfully done and entails a very great hardship to the one undertaking it.

The nervous will complain that they do not feel like work. If left to themselves and told to do absolutely nothing, not even to read, they are sure to dwell upon their infirmities, and grow thereby morose and hypochrondriacal, thus increasing their invalidism. The desire for work should be encouraged in all conditions and in all classes. If one's interest is aroused even to a slight degree, a continuance in the work will develop a desire for occupation. One will never feel like work if one has nothing to do. Work will often accomplish what medicine, however properly applied, will not, for it is not alone that we must earn our bread by the sweat of the brow, but every man and woman should work for the pleasure of it, as well as for the health-giving, brain-expanding results, and the benefit of example. Let idle men and women employ the mind and body in congenial work if they would escape numerous ills to which flesh is heir, for work is necessary to the proper performance of the various functions of the body, a fact not sufficiently dwelt upon by physicians. It is the remedy for the neurasthenic, for work will give occupation to the mind and body, and keep the patient from dwelling upon his infirmities. Exercise will be followed by increase of appetite, the skin and excretory organs will become active, and elimination of toxic materials will be increased.

## TESTS OF HEALTH.

The bane of medicine is a tendency to generalization. We are told in our college days, if we happen to have a sensible teacher, that we must consider the patient rather than the disease, but our textbooks deal with the disease perforce, and we insensibly take our cue from them and fall into the rut of treating tuberculosis or typhoid fever rather than the tuberculous or typhoid patient. The same is true in our counsels regarding right living to the well. Because exercise is, generally speaking, beneficial, we fall into the habit of advising it for everybody; because alcohol in excess is bad for all, and even in moderation for many, we make ourselves disagreeable by forbidding the least indulgence to everyone regardless of individual conditions. It is time this was changed. We should learn to discriminate and to recognize the broad fact that all men are not alike. Each indi-

vidual is a law unto himself in the matter of health, and until we appreciate this truth there will be little progress in the exercise of personal hygiene. One of the first steps in this individualization of hygiene is obviously the establishment of a test of health, one which may be applied to determine how far from or how near to the danger point each individual may be.

In an article on "Individual Factors in Hygiene" in the *Boston Medical and Surgical Journal* of June 15, 1905, previously commented upon in these columns, Drs. Cabot and Brown refer to two possible tests as perhaps worthy of more careful study. "We have noticed," they write, "in quite a number of persons that information of some value can be obtained by noting the degree of infection of their hangnails. Everybody has some hangnails, but when the individual is below par, they begin to get inflamed. Another possible test is the condition of the reflexes, some of the minor reflexes especially. In the last report of Phipps' Institute for Tuberculosis there is an account of the reflexes of tuberculous patients, especially the hypothenar reflexes. We have watched in ourselves for some time the condition of this reflex as compared with our own general condition, and are beginning to watch it in some other persons, too. Perhaps certain individuals can measure their condition by noting the condition of their reflexes. One of us finds that when he loses sleep or is overworked this hypothenar reflex comes out very prominently; scratching the ulnar side of the forearm with a pencil makes the abductor minimi digiti stand out. When he is in first-rate condition the reflex cannot be elicited."

## THE NEED OF SLEEP DURING SCHOOL LIFE.

Growing youths, like men, although to a lesser extent, differ in their need of sleep. As a general rule, however, the lad at school between the ages of 13 and 16, requires nine to ten hours of sleep. The curriculum of schools now is extremely trying. Not only has the standard of education considerably advanced, but sports hold such a high position in all schools of note, that the day is wholly taken up by physical and mental exercise of so strenuous a character that a sufficiency of sleep to recuperate exhausted nature is a *sine qua non* in the preservation of health. Dr. Dyke Acland recently read a paper in London on the matter (*Medical Times and Hospital Gazette,* June 3, 1905), in which his conclusions were based on the forty great high-class schools of Great Britain, as well as on the four best schools of America. The results gathered by this inquiry showed that though head masters, medical officers of schools, and physiologists were of the opinion that growing boys needed nine to ten hours of sleep, yet in many instances the time of quiet in the dormitories was considerably less than this. All the four American schools reached the highest standard—9½ to 10 hours—while in many of the English schools the time for sleep was as little as 8 to 8½ hours, and in a few cases even less, only two reaching the American standard. As remarked above, growing boys need a large amount of sleep, and when this is denied them, neither their bodies nor their minds can develop properly. Our English contemporary points out that this lack of hours of rest falls most heavily on the clever boys who by reason of their ability are raised to higher forms in which the time given to school work is longer, and asks if this may not explain in some measure the disappointing mediocrity in later life of the boy who gave promise of brilliant mental capabilities.

A conference of masters and medical officers of the great schools of England is to be called to consider the subject, a course fully justified by its importance.

## THE HISTOLOGICAL BASIS OF ACROMEGALY.

While enlargement of the pituitary body has been observed in the large majority of cases of acromegaly in which post-mortem examination has been made, such enlargement has been wanting in a small minority. Besides, in another small number disease or destruction of the hypophysis has been unattended with symptoms of acromegaly. Accordingly, opinion is not unanimous as to the etiological relations between the one condition and the other. Of other hypothetical explanations—namely, that which makes the disease dependent on changes in the nervous system, that which regards it as an anomaly of growth, that which makes an increase in the vascular canals of a large and persistent thymus gland the etiological factor, that which assumes loss of function of the organs of generation, with the deflection of an excess of blood to the extremities and consequent hypertrophy, and that which regards disease of the thyroid gland as the causative factor—all are even less satisfactory than that which attributes the symptoms to disease of the hypophysis. More recently the view has been put forward that acromegaly is due to excessive functional activity of the cellular elements of the anterior lobe of the pituitary body as indicated by multiplication of the chromophilic cells. A case that lends support to this view has recently been reported by Dr. Dean D. Lewis (*Bulletin of the Johns Hopkins Hospital,* May, 1905). The patient was a man 46 years old, in whom symptoms of acromegaly had been noticed for six years, death resulting from cerebral embolism and secondary hemorrhage, complicating multiple valvular disease of the heart. Although the hypophysis presented a normal appearance macroscopically, it was found on histological study that the chromophilic cells were increased in number and irregular in distribution, while the stroma was reduced in amount. It seems probable, further, that the changes described in other cases as adenoma, sarcoma, and other forms of neoplasm, have been, in reality, of the same character.

**Borrowing Trouble.**—Jersey City officials are said to be getting disturbed over the transportation of patients from New York City to the sanatorium for consumptives, which New York is about to open in Orange county. At a recent meeting of the Jersey City Health Board a resolution was offered regulating the movements of consumptives while in Jersey City. The resolution requires the railroad company which will transport the patients to carry them across the river in boats specially set apart for their use and forbid that they be allowed to make their way to trains through the station rooms or passageways or to ride to or from the farm where the sanatorium will be located in the trains run for general passenger traffic.

# News of the Week.

**Yellow Fever in New Orleans.**—A number of cases of yellow fever have been reported from the Italian quarters of New Orleans known as Little Palermo. Up to July 25 there had been 154 suspected cases with 32 deaths. The section affected covers eighteen squares, and provision has been made for the disinfection of all houses in that section, the screening of all cisterns, and the killing of all mosquitos. Dr. Souchon, President of the Louisiana Board of Health, is reported to have said that the fever was brought from Belize. Quarantines have been declared against New Orleans by the State boards of health of Texas, Alabama, Florida, and Mississippi. Texas has, as usual, instituted a genuine medieval quarantine, fumigating all New Orleans mail before distribution, prohibiting railways from bringing passengers from New Orleans into Texas, and establishing inspection stations at every railway entrance on the eastern border of the State. Mississippi is working in the same old-fashioned way, with shotgun quarantines, but the authorities in Mobile propose to commit such persons as arrive there to a hospital, where they will remain under scrutiny for five days—the usual period of incubation for yellow fever. If any of these develop yellow fever they will be screened from mosquitos and treated.

**The California State Medical Society.**—The attempt recently made to obtain a charter for a new State Medical Society in California was made by certain Eclectic physicians of the State. The regular Medical Society of the State of California was incorporated in 1870. This society, acting in harmony with the Homeopathic Society of the State, secured the enactment (in 1901) of a medical law, requiring the passing of an examination as a requisite for license to practice. Many of the Eclectic physicians of the State are opposed to any legislation which tends to restrict the practice of medicine by any one, and some of them recently filed with the Secretary of State an application for a certificate of incorporation under the name of the "Medical Society of the State of California." The Secretary of State, however, refused to grant these articles of incorporation, for the reason that the regular State Society was incorporated under the same name. All the papers in the case were turned over to the Attorney General, and the matter is now in his hands.

**The St. Louis Skin and Cancer Hospital.**—On July 1 the St. Louis Skin and Cancer Hospital opened its doors for the reception of patients. This institution, situated on the southeast corner of Jefferson and St. Charles street, consists of a completely equipped hospital of forty beds, and an outpatient or dispensary service. As the title indicates, only skin and cancerous diseases will be treated. The institution is founded upon the research idea for cancer and allied types of malignant diseases. A pathologist, who will devote all of his time to the needs of the hospital, has been appointed, and he will conduct such scientific investigations as the opportunities of the hospital and clinic will permit. A training school for nurses has been established in connection with the hospital. Inoperable and incurable cancer cases, as well as the operable ones, will be admitted to the hospital. The Society hopes, in the near future, to have a home, situated somewhere in the suburbs of the city, for the former cases. The following medical staff has been appointed: Drs. G. Baumgarten, N. B. Carson, J. R. Clemens, M. F. Engman, A. E. Ewing, E. C. Burnett, W. E. Fischel, Frank R. Fry, George Gellhorn, John Green ,John B. Keber, F. J. Lutz, Guthrie McConnell, H. G. Mudd, Greenfield Sluder, J. B. Shapleigh, Ellsworth Smith, Jr., Justin Steer, and Fred Taussig.

**New Hospital for Bermuda.**—Although a lunatic asylum was established in Bermuda as long ago as 1846, and has a daily average of fifty-two patients, a small cottage hospital in the outskirts of Hamilton, the capital, which is kept up by voluntary subscriptions, is the only provision in the way of hospital accommodation. There has been, however, so large an increase in the population of recent years, and the islands have become such a favorite holiday resort for tourists from the United States, that it has begun to be realized that the time has arrived for the establishment of a general hospital, to be supported partly by a subsidy from the general revenue of the colony and partly by the fees of paying patients. A committee of the General Board of Health and others have accordingly drawn out a scheme for the consideration of the Executive, and as soon as the question of site for the extension of the existing hospital or for the erection of a new one has been decided, it is the intention of the Governor to place the matter before the Legislature.—*British Medical Journal.*

**Payment for Special Medical Services Rendered Naval Officers.**—Rear Admiral Lamberton recently sent to the Naval Department a bill for $327 received from an oculist. The Secretary of the Navy sent the case to the Controller of the Treasury for an opinion. This officer ruled that, although the law prescribes that officers must be treated by naval medical officers, in this case such treatment was impossible, because none of the medical officers was an expert oculist; the resort to special treatment was therefore justified. But the law also prescribes that an officer cannot be reimbursed for medical expenses unless he was on duty at the time they were incurred. Admiral Lamberton will accordingly have to pay out of his own pocket so much of the oculist's bill as relates to the three months during which he was on sick leave. The remainder of the account will be paid by the Government.

**Crichton Browne *vs.* Osler.**—In an address before the Public Health Congress in London on July 20, Sir James Crichton Browne adduced many instances in disproof of the Osler theory that the world's effective vitalizing work was done between the ages of 25 and 40. Much of the world's best work, he said, had been done by men over 40. If the world were deprived of their work it would go back to the twilight of ages ago. As a good working hypothesis, he said, we should regard the normal term of man's life as one hundred years, and every child should be brought up impressed with the obligation of living to this age, and should be taught to avoid irregularities in living which tend to prevent the attainment of this ambition.

**Ambulance Accidents.**—On July 6 there was a collision in Brooklyn between a trolley car and a Seney Hospital ambulance, in which two surgeons were injured. A week or two before that a surgeon of the Cumberland Street Hospital was injured in the same way, and about the same time there was a collision between a car and another Brooklyn hospital ambulance in which the driver and surgeon were thrown out but not seriously injured. On July 15 a Lebanon Hospital ambulance was rammed by a Fordham trolley car and mashed to bits. The doctor and driver, together with a patient were thrown out. The doctor and driver were badly cut and bruised, but the patient, who

already had a bad scalp wound, received no further injuries. The next day an ambulance from the Harlem hospital was struck by a Third Avenue electric car, and the driver and surgeon were thrown out and slightly injured. The ambulance was a new one which had been presented to the hospital a month ago, in place of one that had been wrecked by a Second Avenue electric car at 125th Street.

**Seaboard Air Line Surgeons.**—At the closing session of the meeting of this association, held at Old Point Comfort on July 13, the following officers were elected: *President*, Dr. G. Neuffer of Abbeville, S. C.; *First Vice-President*, Dr. W. F. Monroe of Sanford, Fla.; *Second Vice-President*, Dr. G. G. Holliday of Portsmouth, Va.; *Third Vice-President*, Dr. J. W. Palmer, of Airley, Ga.; *Chairman of Executive Committee*, Dr. Southgate Leigh of Norfolk, Va. The association meets next year at Savannah, Ga.

**The Death Rate of New York** for the week ending July 22 was twenty-eight in a thousand, said to be the highest since 1901. The total number of deaths was 2,119, as against 1,726 for the corresponding week of last year. Of these 151 were caused by sunstroke and 109 by heart disease. Spinal meningitis claimed twenty victims, two less than for the corresponding period last year. The high death rate was due directly and indirectly to the intense heat which prevailed last week.

**Suspected Plague Ship Quarantined.**—On the arrival in this port of the British steamship *Indrani* it was learned that since her departure from Yokohama in April two sailors had died at sea of what was suspected to be bubonic plague, and that a third man was ill. The vessel was held in quarantine until she had been thoroughly fumigated, and all the crew were sent to Swinburne Island, where they will be detained until any danger of possible infection is thought to have passed.

**New British Red Cross Society.**—A meeting was held at Buckingham Palace on July 17 for the purpose of organizing a new Red Cross society under the name of the "British Red Cross Society." Queen Alexandra presided and delivered a speech outlining the objects of the organization, and appealing to the women of the empire to take up the work. In time of peace, she said, the society would act separately from the War Office and the Admiralty, but would be under the control of these departments in time of war. A resolution was passed authorizing the appointment of an executive committee, of which it is expected Sir Frederick Treves will be chairman.

**Honors for American Surgeons.**—At a special graduation ceremony at Edinburgh University last Saturday the honorary degree of Doctor of Laws was conferred on William Stewart Halsted, Surgeon in Chief of the Johns Hopkins University of Baltimore; Cameron of Toronto, Shepherd of Montreal, and W. W. Keen of Philadelphia, all of whom were attending the celebration of the quarter-centenary of the Royal College of Surgeons.

**A Mother of Twenty-five Children.**—A woman resident in Mountain Top, Pa., who died recently at the age of forty-seven years, had given birth to twenty-five children. She was married when she was fourteen, and the first baby was born fourteen months afterward. There were but two sets of twins in all the twenty-five, and all are alive now but seven. Some of the eighteen survivors are married, and twelve grandchildren also survive.

**Mr. Edward T. Devine,** General Secretary of he New York Charity Organization Society, Professor of Social Economy at Columbia University, Director of the New York School of Philanthropy, and Editor of *Charities*, was elected President of the National Conference of Charities and Correction at its session in Portland, Ore., on Wednesday.

**Fatal Accident in a Women's Hospital.**—The roof of the chapel of the Women's Hospital at Fermo, Italy, fell in while mass was being celebrated, on Sunday morning, two weeks ago. Sixteen women and fifty children were killed, and sixteen women and a large number of children were injured.

**Dr. Horace Newton Allen,** retiring envoy extraordinary and Minister Plenipotentiary from the United States to Corea, has returned to this country. He was Minister eight years and in the Consular and Diplomatic Service for fifteen years. He resided in Corea twenty-one years, having gone there originally as a medical missionary.

**American Medical Editors' Association.**—The annual meeting of this Association was held in Portland, Oregon, July 10, under the presidency of Dr. Harold N. Moyer of Chicago. The following officers were elected: *President*, Dr. H. Waldo Coe of Portland, Oregon; *Vice-presidents*, Drs. James Evelyn Pilcher of Carlisle, Pa., and Frank P. Foster of New York; *Secretary-Treasurer*, Dr. J. MacDonald, Jr., 92 William Street, New York. The next annual meeting will be held in Boston in June, 1906.

**New Portsmouth (Ohio) City Hospital.**—The Hempstead Academy of Medicine of Portsmouth, Ohio, has passed a resolution urging the City Council to take early action in the matter of building a new city hospital, and promising the support of the profession.

**Alliance (Ohio) City Hospital.**—The staff has elected the following officers: *President*, George B. Haggart; *Vice-president*, J. N. Nelson; *Secretary*, W. C. Manchester; *Treasurer*, John K. Tressel.

**Census of Physicians.**—The Academy of Medicine of Toledo has taken a census of all physicians in Lucas County, Ohio, both regular and irregular. Many physicians who had a license from the State Board had not had it recorded in the Probate Court. They were notified to do this.

**The Wayne County (Mich.) Medical Society.**—The list of officers recently published in this column as of this society was that of the Homeopathic Practitioners' Club. The officers of the regular county society are: *President*, Dr. A. E. Carrier; *Vice-president*, Dr. C. A. Aaron; *Secretary-Treasurer*, Dr. Wm. J. Stapleton, Jr.

**A Lawn Fete in Aid of St. Francis' Hospital of Evanston, Ill.,** which was given by the auxiliary association recently, was a success financially, the receipts exceeding one thousand dollars. This money will be used to aid patients of the hospital who are unable to support themselves until some permanent means can be found for providing for them.

**The Constitution of the A. M. A.**—At a meeting of the House of Delegates of the American Medical Association in Portland, Oregon, July 13, Dr. W. H. Sanders of Alabama moved that a committee of five be appointed by the chairman to consider the validity of the present constitution of the Association. The other delegates, however, did not appear to regard the question of validity as of any special importance and promptly laid the motion upon the table. What's the constitution between friends, anyway?

**Circular on Infant Feeding.**—A little over a month ago the Illinois State Board of Health issued a circular on infant feeding. This edition has been exhausted, and a new one has now just

been issued. The great demand made by the physicians of the State speedily exhausted the first edition. Requests for this circular have been received from every State in the Union. The Health Department of Indianapolis has requested the privilege of purchasing several thousand copies for distribution in that city.

**Increased Death Rate in Boston.** A large increase in Boston's death rate for the week ending July 22, over the corresponding week of last year is reported by the Board of Health. Sixteen deaths were the direct result of the high temperature, and death in many other cases was hastened by the heat. The total number of deaths reported for the week was 239, against 195 for the corresponding week of last year.

**Association of Municipal Engineers and Hygienists.**—A society formed of municipal engineers and hygienists of the French-speaking countries of Europe will be founded at a congress to be held in November, 1905, in Paris.

**Obituary Notes.**—Dr. William W. Bass, one of the oldest graduates of Middlebury (Vt.) College, died July 21 at his home at Dorchester, Mass., after a long illness. Dr. Bass was born in Middlebury, Vt., in 1810.

Dr. Anna Frances Donohue of this city died July 20. She was born in Newburgh, N. Y., in 1873, and was a graduate of the New York Medical College and Hospital for Women in 1894, and was attending physician to the same institution.

Dr. William O. Mendenhall of Richmond, Ind., died July 18, at the age of seventy-one years. He was a graduate of Rush Medical College, Chicago, in 1870.

Dr. Thomas G. Horn of Colorado Springs died July 14, at the age of seventy-eight years. He was a graduate of the Medical Department of Washington University, St. Louis, in 1868.

Dr. O. B. Harriman of Hampton, Iowa, died July 9. He was born in Warren, N. H., September 29, 1836. He was graduated from the Dartmouth Medical College in 1860, practised medicine at Rockford, Ia., for a few years, and moved to Hampton in 1865. He was the first president of the Franklin County Medical Association.

Dr. Robert Dunn McIlwaine of Petersburg, Va., died July 13, at the age of forty-two years. He was a graduate of the Medical Department of the University of Virginia in 1885.

Dr. William S. White of South Omaha, Neb., died July 15 at the age of sixty-one years. He was a graduate of the Medical Department of Washington University, St. Louis, in 1872.

Dr. Herman J. Schiff of this city died suddenly at Alexandria Bay on July 24. He was born in New York in 1863, and was graduated from the Medical Department of Columbia University in 1884. He served as interne at Mt. Sinai Hospital, and at the time of his death was attending surgeon to that hospital and to St. Mark's.

Dr. Joseph Burr Bennett, one of the oldest homeopathic physicians of Brooklyn, died on July 23 in his eighty-ninth year. He retired from practice many years ago.

Dr. Benjamin Edge died at his home in Jersey City on July 25. He was born May 17, 1851, and was sent to London, where he received his early education at Clapham College. Returning to this country, he completed his medical studies at Bellevue Hospital, receiving his degree in 1879. In 1884 Gov. Abbott appointed him a member of the State Council of Charities and Corrections. In 1901 Gov. Voorhees made him a member of the State Reformatory Commission.

## OUR LONDON LETTER.

(From Our Special Correspondent.)

IMPERIAL CANCER RESEARCH FUND—LEAGUE OF MERCY—MEDALS FOR TROPICAL RESEARCH—HOSPITALS AND APPEALS—COLLEGE ELECTION—SUNDAY FUND—SPECIMENS BY POST—SIR O. LODGE ON TEETH AND BRAINS.

London, July 7, 1905.

On Wednesday the Prince of Wales, as President, took the Chair at the third annual meeting of the Imperial Cancer Research Fund. Many important and interesting statements are made in the report. Records of 5,000 cases examined microscopically have been obtained from various hospitals. The statistics lead to the inference that the frequency of sarcoma increases as life advances in a manner analogous to that of carcinoma. It is not at present possible to decide if cancer is really increasing, but no known form of infection determines the number of deaths it causes. It is stated in the report that all the features of cancer can be produced experimentally, but it still debated whether it arises in small circumscribed groups of cells from which all subsequent growth proceeds, or if a transformation of tissues surrounding the primary site also takes place at the commencement. In recent experiments the features of cancer have been reproduced by growths originating in a few isolated cells introduced into healthy mice. Under artificial propagation a malignant growth is an independent organism and behaves like a succession of "organisms without organs" and may be compared to a succession of generations of animals maintaining the species, rather than to the growth of the individual, but it can only maintain its existence in the species in which it has arisen. The power of growth is amazing. A mouse tumor has produced more tissue than would equal several thousand mice; so that the amount necessary to kill an individual is infinitesimally less than the power of division in the cells. The enormous cell division proceeds, in artificial propagation, in young and healthy animals, quite as well or better than in older ones. The experiments show no analogy to exist with any infective diseases, and the parasite hypothesis has no support.

The action of radium and the processes responsible for the disappearance of some tumors in mice subjected to it have been studied, and it seems that it does not act in a uniform manner under experimental conditions apparently identical. Radium has no specific action on cancer cells, but it acts on the nourishing and supporting tissues of a tumor, and if this action coincides with a favorable phase in the cells, a tumor might be absorbed, as is observed when a growth spontaneously disappears.

Sir William Church moved the adoption of the report, and referred to the statistics as confirming the conclusions of last year and to the remarkable results of experiments. The perpetual multiplication of the cancer cells in favorable conditions was not, he said, found at all times, and the results showed the necessity for further study of this excessive proliferation and reproduction. This property separated cancer from infective diseases, in confirmation of which healthy mice kept for long periods with those inoculated had not taken the disease. The action of sera had been studied. No definite action had been obtained by injecting sera into cancerous mice. Radium and radioactive solutions had been also studied, and though both exercise an influence on the growth and development of both normal and abnormal tissue, there is so far no proof that radium emanations have any specific effect on tumor tissues. The solutions could not safely be introduced into the body in quantity enough to produce any effect. He thought he might venture to say that the work done in the past year marked real progress. The malignancy of cancer seemed to reside in the power of the cells for unlimited growth, and if they could find out the nature of this they might succeed in limiting this proliferation and thereby neutralizing the malignancy. The committee was indebted to Sir William Ramsay, Professors Borel, Jansen, von Leyden, Michaels, and also to the Indian, Colonial, and Foreign offices as well as to other bodies and private individuals. The resolution was seconded by Mr. John Tweedie and unanimously carried. Thanks were also voted to the committee and the honorable treasurer. The latter's report appealed for further funds, as it had been necessary to draw upon capital.

The Prince of Wales, in reply to a vote of thanks for presiding, made a sympathetic and earnest speech, thanking the bodies and individuals who had assisted in the work. He also expressed gratification that Sir W. Church had consented to continue on the executive committee, of which he had been reelected chairman.

There was a large gathering on Saturday in the grounds of Marlborough House in response to an invitation of the Prince and Princess of Wales to the garden party in connection with the League of Mercy. The Prince made a speech in which he thanked the workers for the League, and expressed gratification at another successful year in which £14,000 had been handed over to King Edward's Hospital Fund, making £46,000 during the five years of the League's existence. On Tuesday the King sanctioned a number of awards in the Order of which His Majesty is sovereign.

Princess Christian, as President of the Liverpool Tropical School, received Sir A. Jones and Professors Ross and Boyce and presented medals to Dr. Laveran of Paris, Sir P. Manson, and Colonel Bruce.

The removal fund of King's College Hospital is to benefit by £20,000 from the estate of the late Miss M. F. Hasker, on condition that one of the blocks be named after deceased and a mural tablet placed on it recording the benefaction.

The Bristol Royal Infirmary has received an anonymous donation of £500.

The Middlesex Hospital has considered the decision of the King's Fund respecting the maintenance of medical schools, and the governors have affirmed the desirability of assisting their school which has been carried on for the last 70 years. It was agreed to procure the authority of subscribers for the Board to set apart a portion of their contribution to this purpose Already about 200 subscribers have assented to this proposal and only five have declined to do so.

At the dinner of the Royal Hospital for Incurables it was stated that it has become necessary to reconstruct the drainage and that this is likely to cost some £6,000. The institution accommodates 200 inmates and gives small annuities to upwards of 700 persons. Donations to the amount of £3,872 were announced.

About £2,000 is appealed for to rebuild a hospital at Karnal which was partially destroyed by the recent Indian earthquake. At a meting to promote this object Sir T. Stevenson compared this "trifling sum for an institution of 25 beds with the enormous sums raised in London where £1,000 is sufficient for only one bed."

Yesterday there was an election at the Royal College of Surgeons to fill four vacancies on the Council. Messrs. Edmund Owen, Golding-Bird, Godlee, and Harrison Cripps were elected.

The amount of the Hospital Sunday Fund collections transmitted to the Mansion House up to yesterday morning reached £7,000. More will be coming in during the next week or two.

It is proposed that the British Medical Association should try to obtain a Royal Charter.

The Postoffice regulations as to the transmission of pathological specimens have not always been duly observed, and the authorities have called attention to the fact that any one sending deleterious material otherwise than as provided for by these regulations is liable to prosecution, even a patient sending something to his doctor, or the latter sending to a laboratory. The rules are made for the protection of the public and the postal servants, and cannot be considered unnecessary.

Sir Oliver Lodge, speaking at Birmingham yesterday at the opening of a new dental hospital, said he asked an eminent dental surgeon why our teeth were going so bad, and he replied that it was due to the development of brain. The more of brains one had the less of teeth. It certainly did appear, said Sir Oliver, that teeth were among those parts of the human organism which were tending to become extinct, like the toes, for all our toes, he expected, would go if we persisted in wearing boots.

Personally he did not think that we had too much brains. The remedy rather was a little more brain. People said we had too much science because we had learned how to make smoke and noise, and spoil the face of the country, but we had really just enough science to make a mess of things and not enough to put them right again.

## OUR PARIS LETTER.

(From Our Special Correspondent.)

ELECTION OF GRÉHANT, YERSIN, AND WERTHEIMER—OSTEOPERIOSTEAL LIPOMATA—PRESERVATION OF THE OVARIES AND UTERUS IN OPERATIONS ON THE ADNEXA—PALPEBRAL REACTION TO SYPHILIS IN MACAQUE MONKEYS—EXPERIMENTAL SYPHILIS AND ITS MICROBE—COLONIAL CONGRESS—NECROLOGY: CHARLES MAURIAC—MONUMENT TO PROFESSOR TARNIER.

PARIS, June 30, 1905.

The Academy of Medicine, at its meeting on May 30, elected as a titular member in the section of anatomy and physiology Gréhant. At the following meeting two national correspondents were elected,—Yersin of Nha-Trang, and Wertheimer of Lille.

The Surgical Society has devoted several meetings to the discussion of osteoperiosteal lipomata. Routier reported the observation of a boy 13 years old who had a subclavicular tumor; this was fluctuating, a little painful, and was fastened to the external third of the clavicle by a pedicle. The diagnosis of cold abscess was made but two successive punctures did not give any result. The tumor was removed. It was then seen that the growth was a lipoma which was attached to the clavicle by a pedicle, infiltrated with osteoid tissue and from which fibrous prolongations spread out in the shape of a fan.

Guinard called the attention of the society to a variety of osteoperiosteal lipoma of congenital origin; he had observed this tumor in a girl of seven months. It was situated in the subspinous fossa of the scapula. It was interesting to note that recurrence took place three years after its removal. Grave symptoms developed in the evolution of the primary tumor and in that of the recurrent tumor. Guinard thought that recurrence took place from a lobe of the tumor which had not been removed at the first operation. As to the occurrence of the symptoms, he thought this a mere coincidence, believing that the tumor had grown, in both cases, under the influence of a general intoxication. Nélaton, Broca, Delbet, Kirmisson, and Monod, reported personal observations of osteoperiosteal lipomata, after which Monod took up the discussion again. He thought that the name subperiosteal lipoma ought to be reserved for those tumors which are situated beneath the periosteum and in more or less extensive contact with the bone. Walther ended the discussion by an interesting observation of an osteoperiosteal lipoma of the thigh, very probably congenital, with trochanteric insertion, in a boy 15 years old.

At the last three meetings the Surgical Society has discussed a communication from Tuffier concerning the preservation of the ovaries and uterus in operations on the adnexa. Tuffier proposes to replace uteroadnexal castration by the simple removal of suppurative or infected tubes, preserving the uterus and ovaries. There is no theoretical objection to this method, and practically the results obtained in thirty-two cases of this investigator have been excellent. Operative mortality shows one death in the thirty-two cases. Operative sequelæ are simple and there have been only two recurrences. Routier declared that he was not satisfied by the proceeding defined by Tuffier; he believed in an absolutely conservative treatment or in one absolutely radical. Faure declared that this question had been discussed for a long time by gynecologists. He said that the difficulties concerning this problem related to the condition of the ovaries. He thought that the determination of pain in the course of the clinical examination ought to serve as the criterion—for want of better evidence—and ought to direct the conduct of the surgeon. Personally he was in favor of the radical treatment.

At the Hospital Medical Society, Thibierge and Ravaut offered an interesting communication concerning the palpebral reaction to syphilis in macaque monkeys. These men have determined that the free border of the eyelid always reacts even when simultaneous inoculation of other parts may be negative. The palpebral reaction of this species of monkey to syphilis is sufficiently differentiated to be applicable to the diagnosis of lesions, the nature of which cannot clinically be determined.

At the Society of Internes of the Paris Hospitals Metchnikoff also communicated his researches in experimental syphilis. In the case of 14 chimpanzees, all contracted syphilis after incubation of from 22 to 35 days. Out of 14 animals, seven showed secondary phenomema; but these animals are so delicate in our climate that tertiary symptoms have not been observed. It has been proved that syphiletic virus does not pass through bougies which allow the passage of the virus of peripneumonia of cattle. Heated to 48°, it loses its virulence; it does not lose it when mixed with glycerine. The recent researches of Schaudinn verify the conclusion that syphilis is caused by the spirochæta pallida of Schaudinn, and is pathogenic for the human being, for anthrophoids, and for certain varieties of the lower order of monkeys.

At the Colonial Congress held in Paris, June 5 to 9, much time was devoted to medicine. Three very interesting questions were considered: Medicine and Colonial Hygiene; International Hygiene and Prophylaxis; Pharmacy and Materia Medica. Regnault presented a paper on hemoglobinuric bilious fever. Following this lecture came a discussion. The Colonial Congress decided that various obscure points ought to be cleared up in relation to this disease. Dye gave a report on the transmission of yellow fever due to the mosquito (stegomyia fasciata). The sleeping sickness was comprehensively discussed by Brumpt. A very interesting report of Margain on the

régime of foreigners in the colonies was read. He showed that alcoholism and absinthism were the most frequent causes of mental disturbance. As there are no insane asylums in the colonies, these patients had to be brought back to France. Margain thinks that asylums for these patients should be built in the colonies. He also believes that special infirmaries should be built for foreign soldiers in time of war.

Charles Mauriac, one of the masters in the hospital, and whose name has become inseparable from the Ricord Hospital, is dead. He was the author of the following works: Lessons in Primary and Secondary Syphilis; Treatise on Tertiary and Hereditary Syphilis; and Treatment of Syphilis. Mauriac published besides, a large number of monographs on venereal diseases and on gonorrhea.

The monument to Tarnier, who was professor of clinical obstetrics at the Faculté de Médecine in Paris, was dedicated June first. Bienvenu-Martin, Minister of Public Instruction, presided. At the base of the monument were engraved these words: "To the Master Who co - secrated His Life to Mothers and Infants, from His Colleagues, His Pupils, His Friends, His Admirers." Brouardel presented the monument to the city of Paris in the presence of the Vice-President of the Municipal Council of the Prefect of the Seine, of the Director of Public Assistance and of Pinard and Budin, delegates from the Faculté and the Académie de Médecine.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

THE WOUNDED ON THE RUSSIAN CRUISERS IN MANILA HARBOR—THE MORALE OF THE CREWS—SMALLPOX FROM THE UNITED STATES.

MANILA, P. I., June 8 1905.

THE inhabitants of Manila have had an excellent opportunity to observe the effect of the Japanese gunnery upon some of the Russian vessels that took part in the great sea fight in the Korean Straits. On Saturday evening, June 3, six days after the engagement, three Russian cruisers, the *Zemtschug*, the *Aurora*, and the *Oleg*, put into Manila Bay in a badly damaged condition. The vessels were under the command of Admiral Enquist, who is the only Russian admiral that was in the fight who was not either killed or captured. The ships awaited quarantine inspection by the Manila quarantine authorities. No quarantinable diseases were found and in consequence pratique was granted at once. After this the first concern was for the wounded. Of these there were 160 upon the three ships. Fifty-three of them were in need of immediate hospital care. The U. S. Naval authorities offered the use of their new hospital, which has just been completed at Cañacao, Cavite. The Insular Government tendered the use of its Civil Hospital, the Army offered the First Reserve Hospital, and the use of the new St. Paul's Hospital, which is just about to be opened, was also offered. In view of the fact that the status of the vessels, as to whether they could remain long enough for repairs, had to be determined by the Washington authorities, it was decided to remove, for the first at least, only 53 of the worst cases. These were taken to the Naval Hospital at Cañacao. One of the vessels had 13 men killed in action, one 14, and the other 15. The *Aurora*, the flagship, had her captain killed, and upon the *Oleg* there were two officers killed. Of the 53 wounded taken to the Naval Hospital, some 20 had fractures of the various bones, most of which were compound, comminuted, and infected. In fact the wounds of all the men mentioned above were infected before they left the ships. So far as observed, the wounds were all caused by either fragments of shells or splinters. Of the entire number not one could be attributed to small bore guns because they were all of a lacerated character both at the point of entrance and at that of exit. Most of the injured had more than one wound. One man, who was a member of a gun crew of nine was its only survivor, and he had 35 wounds.

The appearance of the men as a whole, even those who had received no physical injuries, was pitiable in the extreme. They all seemed broken in spirit and they had the appearance of having undergone a severe mental strain. Many of them had no doubt had little or no sleep for the ten days previous, and the mental anxiety which they had undergone since leaving Russia, over six months ago, has told upon them severely. From a physical standpoint it would be correct to say that they had originally excellent physiques, but from an intellectual standpoint it could not be said that they possessed the features that indicate a high grade of mental development.

The facilities for treating the wounded aboard were not good and the supply of dressings was inadequate. The space allowed a surgeon of a war vessel appears to be entirely too small, and unless much better accommodations are provided for doing aseptic work the same poor results must be expected in the future. Upon the Russian vessels one of the greatest drawbacks was the lack of ventilation, and this, coupled with the fact that the ships were painted black, made the heat in the compartments occupied by the wounded almost unbearable. From the meager information obtainable about the vessels at the present time, it appears that they were not designed with the view of using them in tropical countries, and for that reason the men underwent many unnecessary hardships.

The U. S. Army Transport *Sherman* arrived in Manila June 2 from San Francisco with a case of smallpox aboard in the person of one of the cabin stewards. One case and one suspect had already been taken from the vessel at Honolulu. In view of the fact that the cabin passengers were most exposed and therefore most likely to convey the infection it was deemed necessary to remand the vessel to Mariveles for the disinfection of all persons on board and their effects. Over 1,500 people were treated.

## Progress of Medical Science.

*Boston Medical and Surgical Journal, July 20, 1905.*

**Observations Upon the Actual Results of Cerebral Surgery at the Massachusetts General Hospital.**—After some remarks on the methods pursued in following up the histories of patients after they have left the hospital, E. A. Codman classifies the cases as follows: (1) Operations for removal of a tumor if possible; if not, for relief of pressure symptoms, 28; of these 7 died within two weeks, 11 showed no improvement, 7 were improved, 3 not traced. (2) Operations purely to relieve pressure symptoms, 8; of these 4 died within two weeks, 2 were not improved, 2 not traced. (3) Operations for the relief of epilepsy, 21. Of these 12 showed no improvement, while 9 were improved. (4) Operations for drainage of cerebral abscess, 6. Of these 5 died within two weeks, while 1 was improved.' The author calls attention to the fact that the iodide test often delays the operation for months, and that the public must consent to autopsies if brain surgery is to be advanced. He lays stress upon the necessity of preventive measures against shock, hemorrhage, sepsis, post-operative paralysis, and speech disturbance. The records of this series of cases show that of all brain tumors, very few are removable and that of these the greater number arise from the dura. Rather surprising is the fact that those really removable, as shown by autopsy, are most difficult cases to handle and that in the hands of the surgeons who operated not one of the 28 cases has been successful as a radical procedure. A considerable percentage of those improved was so benefited only by the relief of pressure: the failure to improve the others was due most likely to strangulation of the motor cortex through the trephine hole or to damage done to the brain tissue. Lumbar puncture was not found a satisfactory method of relieving intracranial tension, nor was any good accomplished by exploration in the brain tissue by incision, probing, or the use of aspirating needle unless there was on the surface of the brain some indication of the presence of a cyst or tumor.

**Report on Results of Brain and Cord Surgery.**—Dr. J. J. Putnam considers in outline the five cases of the Codman tumor series in which the greatest improvement has followed operation; also, in a similar way the six best cases of the epilepsy series. He finds in a general way that the cleaning up of the results of old injuries to the skull and its membranes results favorably in a fair number of instances, due to the removal of reflex irritations and the securing of better conditions of local nutrition of the cortex. Results are strangely variable, however, and cannot be predicated in advance. Doubt still surrounds the proposed method of excising motor areas of the cortex in cases with localized aura. The author considers that surgeons with a distinct neurological training are needed to obtain the best results in this class of patients.

**Results in Non-traumatic Surgery of the Brain at the Boston City Hospital.**—W. N. Bullard considers the results in a series of 44 cases, 39 intracranial and 5 spinal, classifying them in a general way as Codman has done for the Massachusetts general series. He confines his detailed observations to the epilepsy series, 18 cases, 3 not being traced. In 12 injury was the apparent cause of the neurosis. Of these 3 were not relieved; in one the result was doubtful, while improvement followed in all the others. Of the 3 non-traumatic cases, one with apoplexy and multiple cysts was relieved; of the 2 idiopathic cases one was improved, while in the other the disease progressed in spite of possible temporary relief. Some of the best results have been obtained in cases of long duration. Cystic cases might be supposed to offer the more favorable prognosis, but from the small number of cases under consideration, the author does not venture any conclusions on this point.

*New York Medical Journal, July 22, 1905.*

**The Value of the Recognition of Errors in Refraction in Functional Diseases of the Nervous System.**—E. D. Fisher asks if there is any rational reason for supposing that errors of refraction, no matter what their intensity, can induce such well-defined diseases as epilepsy, chorea, neurasthenia, melancholia, or general paralysis? In regard to epilepsy, many convulsive seizures often considered as epileptic attacks are not so at all. Many causes may produce convulsive seizures, but they are not epilepsy. It is practically impossible for an irritative eye lesion to produce that true epileptic condition which presents not only convulsive seizures but also impaired mentality, loss of mental concentration, gradual tendency to dementia, and at times delusions of changed personality. We should always rectify any existing ocular abnormalities just as we do those of other organs, but by so doing we do not cure true epilepsy. The same general principle holds true of chorea. The author has never seen the chronic form of this disease affected by correction of refractive errors. Many cases exhibiting choreiform movements may seem to be benefited, but in the acute form the malady is self-limited. In regard to melancholia, the author is unable, from looking over reports of the hospitals for the insane and from his own personal experience, to find direct relation in cases which have recovered to treatment for any special organic disease of the eye, stomach, uterus, or other organ.

**Congenital Absence of the Kidneys.**—The patient of L. W. Glazebrook was a dissipated woman of thirty-eight years who died as the result of a debauch. She had never undergone any surgical operation. The autopsy revealed absence of the left kidney. The right organ was abnormally large, showing the ordinary appearance of the "large white" kidney, weighed eight ounces, and measured six by two and one-half by one and one-half inches. The ureter bifurcated about three-quarters of an inch from the organ, one branch passing upward into the upper lobe, the second downward to the lower. No normally situated pelvis was found, but at the termination of the two separate ureters, there was a distinct pelvis for each. The ureter proper was of normal size and communicated with the bladder at the normal place. No evidence of the left ureter was found on the opposite side of the bladder. In shape the specimen was of a characteristic kidney shape, being in no way deformed. The bifurcation of the ureter near the kidney suggested the idea that it might be a variety of horseshoe kidney, but its shape in no way bore out this suspicion.

**Rapid Healing in Septic Cases, Including the Use of Iodoform Wax in Bone Cases.**—A. T. Mann refers to the advance in modern surgical methods, instancing the use of carbolic acid followed by alcohol in abscess cavities, local conditions thus allowing of union by first intention when opposing surfaces are coaptated. He finds the acid-alcohol method of special service in circumrectal fistulæ. He then refers to the use of iodoform wax as popularized by Moorhof. The wax is made of iodoform, sixty parts, oil of sesame forty parts, and spermaceti, forty parts. The author then describes a series of cases seen in Moorhof's clinic treated with this preparation, and appends some personal experience. He finds that we can clean out the cavities found in conditions of osteomyelitis, fill them with the bone wax, and suture the soft parts over them for first intention union. The wax is gradually replaced by an ingrowth of tissue, largely of bone.

*The Medical News, July 22, 1905.*

**Clinical Features of the Benign Stenosis of the Pylorus.**—H. L. Elsner divides these into functional and organic (congenital or acquired). Functional stenosis are likely to be transitory, the patients being highly neurotic. There are also cases of intermittent hyperchloridria without ulcer in which we assume the presence of pyloric spasm recurring at rather long intervals. Such a spasm may safely be considered secondary in the majority of cases, and its presence must always lead to a strong suspicion of associated organic disease. Congenital organic stenosis follow both immediately or are not long postponed. Persistent vomiting beginning after the ninth or tenth week of life is not due to congenital pyloric stenosis, as most of the latter cases die before the end of the third or fourth month. Ford's modification cannot possibly relieve a stenosis of high degree. Acquired stenosis, intrapyloric, may be cicatricial, fibrous (general or localized), hypertrophic, dependent on ulcer, due to acute inflammation, syphilis, tubercle, non-malignant growths, traction, or distortion. Extrapyloric stenosis may arise from so many causes that classification of them is difficult. A fasting stomach which is found distended and contains food remnants must always arouse suspicion. A leading symptom of stenosis is vomiting. Another symptom of great value is peristaltic unrest. The stomach tube is indispensable as a diagnostic agent. Tetany is a symptom of great value in diagnosis of gastrectasia. The previous history of the patient, age, and heredity must be taken into account. The later in life the stenosis occurs the more likely is it to be malignant. Treatment is embraced in the following propositions: (1) Such foods only to be taken as the dilated stomach with motor weakness can prepare to be forwarded beyond the point of resistance for further digestion. (2) We should strive to prevent stagnation of food with associated fermentation and the formation of organic acids, (3) must empty the distended stomach as far as is possible; (4) prevent tetany and other nervous and distant symptoms; (5) improve the general condition, and (6) treat associated symptoms as they arise by rational and natural methods, including the use of drugs, attempting by these to overcome or counteract the effect of secretory and motor anomalies.

**The Relation of Some of the Metabolic Diseases to Intestinal Disorders.**—T. B. Futcher reviews the main facts we know concerning alkaptonuria and ochronosis and cystinuria. In alkaptonuria the urine, of normal appearance when voided, soon becomes deep brown and ultimately black if exposed to the air. The ingredient causing these changes probably comes from tyrosin and is called homogentisic acid. The condition is in the vast majority of cases (perhaps all) congenital. After it is found that the patient's urine in infancy stained the diaper a dark brown. The condition persists through life. Curiously it is found that a very large percentage of the cases collected have been in the children of first cousins who do not themselves manifest the anomaly. The general health does not seem to be affected. Associated with the condition is ochronosis or pigmentation of the cartilages first described by Virchow in 1866. Cystinuria is a condition characterized by the spontaneous deposit in the urine of hexagonal crystals of cystin. It is not commonly associated with any definite symptoms. Occasionally there are present digestive disturbances, often anemia. Renal calculi may form out of cystin. The substance is commonly related to putrefactive changes in the intestine. Futcher discusses in his considerations of these rare affections many chemical problems, and this part of his paper must be consulted by those interested. He also adds a few words on the topics of diabetes and gout, but considers that intestinal disorders have very little influence in their causation. Acetonuria, however, may be an exception to the truth of this general statement. As far as we are aware at the present time intestinal disorders play no special part in the etiology of gout.

*American Medicine, July 22, 1905.*

**Vicarious Action of the Bowels for the Kidneys in Tuberculosis.**—Lawrence F. Flick and Joseph Walsh call attention to the fact that it has long been recognized that in certain cases of tuberculosis there is a looseness of the bowels not due to ulceration. This looseness has been termed irritative diarrhea and has been ascribed to errors in diet. A careful study of the number of cases which have been under observation a long time clinically, and which have come to autopsy, lead us to believe that in these cases the looseness of the bowels is due to the vicarious action of the bowels for the kidneys, and that nature is really trying to protect the system by this vicarious action. Eleven cases are reported. In all of them there was severe diarrhea usually over a protracted time. In all the intestines were practically normal and the kidneys showed acute alterations. The cases were studied clinically from four weeks to three years; diarrhea lasted from four weeks to eight months. In three cases out of the eleven the autopsy showed the ileum slightly congested; in all the remaining cases the intestinal tract, with the exception of the appendix, was normal. Several forms of nephritis were found, toxic nephritis, parenchymatous nephritis, diffuse nephritis, and interstitial nephritis. In seven cases out of the eleven there were scattered tubercles in the kidneys. The diarrhea was considered to be a vicarious action for the kidneys because no other definite cause was found. The rest of the paper deals with nephritis in tuberculosis, its frequency, its etiology, its symptomatology and its treatment. It is caused by the growth of tubercle bacili in the tissue of the kidneys and by the toxins secreted through the kidneys from other lesions elsewhere. It also may be caused, perhaps, by the dead tubercle bacilli in the process of elimination. The treatment is by means of magnesium sulphate and nitroglycerin.

**A Brief Report on Research in the Writer's Laboratory on Bacterial Toxins and Immunity.**—Victor C. Vaughan based his work upon the theory that the bacterial cell is, in its essential part, a chemical compound made up of many groups. He had endeavored to split up the cell molecule of the colon bacillus into its constituent groups and to study the physiological action of these groups. The result of the work has been to show: (a) That the

colon bacillus even when grown upon proteid-free mediums, contains a highly poisonous group and that animals treated with repeated doses of this group have their resistance to living cultures of the colon bacillus multiplied from two to four times; (b) that a group similar to that mentioned can be obtained from egg albumen and peptone, and that animals treated with this also show increased resistance to the living bacillus; (c) that animals treated with successive doses of that portion of the colon cell left after the removal of the poisonous group acquire a specific immunity to the colon bacillus; (d) that the blood-serum of animals treated with either the poisonous group or the nonpoisonous group of the colon bacillus do not agglutinate the living colon bacillus; (e) that cultures of the colon bacillus contain a fatty acid which either as a free fatty acid or as a neutral soap dissolves red blood-corpuscles.

**Relapsing Fever.**—F. Creighton Wellman shows that this disease has a wide proved distribution in tropical countries. It is quite probable that it has been overlooked in other places or mistaken for other conditions. The parasite is sometimes very scarce in the blood and may be overlooked in many instances. The affection would seem to have as good a claim to be ranked as a tropical disease as has malaria, leprosy, plague, and other diseases which are only partially dependent on climatic conditions for their survival. Practitioners in the tropics should be especially careful to search the blood of suspected patients before making a diagnosis of "double continued fever," etc.

*Journal of the American Medical Association, July 22, 1905.*

**Intravenous Injection of Ergot.**—Torald Sollmann and E. D. Brown report the results of experiments, made chiefly on dogs, to determine the circulatory effects of ergot in therapeutic doses, normally and in the pathological conditions in which the drug is recommended. Intramuscular injections were first employed, but the effect was so slight they changed to the intravenous method, that used by other investigators. The animals were anesthetized, the injections made into the femoral vein, and the blood-pressure tracings taken with a mercury manometer, the connection being filled with 25 per cent. magnesium sulphate. The conclusions reached are, in substance, as follows: The typical effects of the intravenous injection of ergot consist in a large and abrupt fall of blood pressure, followed by a prompt recovery, and generally by a slight and short rise. The volume of the organs varies generally in the same direction as the blood pressure. The changes in the latter are mainly cardiac. This is confirmed by myocardiograms from the intact and excised heart. Ergot causes first a lessening and then an increase of the excursions; both phenomena may occur while the ergot is being injected; the rate of the heart is but little altered. The effect must be directly on the cardiac muscle. There are some oncometric evidence that ergot has a slight vasoconstrictor action, but this is slight and inconstant. There was no evidence of strong constriction or of high rise of blood pressure. With intramuscular injections the preliminary fall of blood pressure is absent. The action is independent of the dose, within wide limits. The relative predominance of fall and rise vary somewhat in different preparations; age, however, does not impair their effect on the circulation. Lowering the blood pressure by any method greatly lessens the effects. Shortly after the destruction of the spinal cord, however, ergot produces a relatively good rise of pressure. Large doses depress the vagus center and the vasomotor endings. It is not acutely fatal, however, in very large doses. The experiments do not point to any useful therapeutic action of ergot in modifying the circulation. The authors, however, do not wish to be understood as denying the clinical evidence in its favor, they merely claim that it lacks experimental evidence in its support.

**Inguinal Hernia of the Bladder.**—After reporting a case in which the included bladder was wounded in operation for hernia, S. C. Plummer discusses the diagnosis of the condition which, in the majority of cases, is unrecognized until operation and sometimes not even after the bladder has been injured. He thinks the reason of this is that we have been taught to consider it a pathologic curiosity and are not sufficiently on the outlook for it. The urinary symptoms should not be neglected, and conditions which lead to suspicions of the presence of the bladder during operation, such as the presence of an unusual amount of fat in the canal, the location of the tumor, the difficulty of separating it from the true hernial sac, the recognition of its musculature when present, the possibility of passing a catheter or sound into the hernia, the large size of the inguinal opening, the frequency of direct hernia, and the difficulty of finding a neck to the true hernial sac, should all be looked for. The paper is instructive in its details of the condition.

**Looping the Cord.**—The frequency of the condition of looping of the cord is estimated by H. C. Jones as rather greater than is usually alleged. He thinks it existed to a greater or less extent in nearly half of the cases he has attended, over 1,400 altogether. He reports a case that seems to him extraordinary. The signs of fetal life had ceased at the end of the seventh month, but delivery occurred at term, and a macerated fetus was born with the cord wrapped four times around the left leg and once around the right. Delivery occurred without rupture of the membranes. He thinks it possible that death of the fetus did not occur immediately at the time of strangulation of the cord. Its condition and the fact that it was carried to term suggest that a low degree of vitality may have existed for a part of the period. He says "it must be apparent that so complicated a looping about the extremities as shown in this case could only have been brought about by instinctive efforts to disentangle them" and compares the impulse here shown with that of animals to free themselves from a tethering rope.

*The Lancet, July 15, 1905.*

**Simplification and Use of Tracheal Injections in Pulmonary Tuberculosis.**—This topic is considered by Mendel of Paris, who notes current objections to the method, viz., that the injections are not easy to give, that laryngologists do not usually treat tuberculosis, and the prejudice against manipulative interference with the trachea. In reply, Mendel states that an injection of non-irritating material, properly given, does not cause cough or other disturbance, and that a simple method is quite within the reach of any medical practitioner. If the tongue of the patient is protruded and held outside the mouth, and if he, at the same time, refrains from swallowing, the pharynx forms a funnel in which the only inferior outlet is the glottis; for the orifice of the gullet is closed, except during the act of swallowing, so that a small quantity of liquid projected *against the wall of the pharynx* runs down into the air passages. A diagram is given illustrating the above anatomical relations. This method the author calls the medial method. He prefers, however, what he calls the lateral method. A syringe is used ending in a tube with a short distal curve of very small radius. The patient is opposite a window. The operator holds the tongue and passes the syringe with the tube horizontal, being careful not to touch the tongue. The outside of the curve is then applied firmly to the base of the left faucial column. The operator presses firmly outward against this so as to steady his hand during the expulsion of the injection. The nozzle of the tube thus rests horizontally in the glossoepiglottic groove, hidden by the base of the tongue. The patient should remain passive, and breathe without effort. The contents of the syringe are discharged with sufficient force against the lateral pharyngeal wall to turn round this wall and thus reach the posterior wall whence they run into the larynx. For the injections Mendel prefers eucalyptol dissolved in olive oil.

**The Chemical Mechanism of Gastric Secretion.**—J. S. Edkins regards it as probable that in the process of absorption of digested food from the stomach a substance may be separated from the cells of the mucous membrane which passing into the blood or lymph later stimulates the secretory cells of the stomach to functional activity. He considers this theory supported by the following observations: If an extract in 5 per cent. dextrin of the fundus mucous membrane be injected into the jugular vein there is no evidence of secretion of gastric juice. If the extract be made with the pyloric mucous membrane there is evidence of a small quantity of secretion. With dextrin by itself there is no secretion. Extracts of fundus mucous membrane in dextrose or maltose give no secretion; extracts of pyloric mucous membrane give marked secretion; dextrose or maltose alone brings about no secretion. If extracts be made with commercial peptone it is found that no secretion occurs with the fundus mucous membrane, a marked secretion with the pyloric mucous membrane; the peptone alone gives a slight secretion. If the extracts be made by boiling the mucous membrane in the different media the effect is just the same—that is to say, the active principle, which may be called "gastric secretion," is not destroyed by boiling.

**The Duration of Life After the Appearance of Albuminuric Retinitis.**—S. Snell states that albuminuric retinitis occurs in about 30 per cent. of all cases of Bright's disease. It seems to be more frequent in males. From a study of the statistics from the practice of other men, and from his own personal experience, he regards the retinal changes as a signpost of the systemic deterioration produced by the renal lesion. It portends a fatal termination, possibly in a few months, rarely deferred for more than two years. An exception to this statement obtains with reference to

cases occurring in pregnant women, for it not infrequently happens that with the termination of gestation, the albumin disappears and the retina clears up, though vision may remain seriously affected. But the condition is not under the circumstances named so fatal to life as in ordinary chronic nephritis. Snell maintains that a sharp distinction must be drawn between private and hospital practice, for those better situated can take the hygienic care requisite in Bright's disease. Moreover alcoholism may play a more important part in hospital patients.

*British Medical Journal, July 15, 1905.*

**Acute Salpingitis Caused by an Inflamed Appendix Bursting into the Mouth of the Fallopian Tube.**—J. Bland-Sutton operated on a patient suffering from pelvic pain accompanied with acute febrile signs. A tender swelling was felt on the right side of the uterus. When the abdomen was opened, the appendix was seen adherent to the fimbriated end of the right Fallopian tube. The tube itself was distended and adherent to adjacent structures. The appendix, tube, and ovary, were excised but their relationship was left undisturbed. Section of the hardened specimen showed that the lumen of the tube was filled with pus. Its coelomic ostium had been firmly occluded and the fimbriæ were withdrawn into the lumen of the tube. A narrow channel led from the interior of the appendix through its wall, near the tip, directly into the lumen of the tube. The patient had an uninterrupted recovery.

**Case of Cutaneous Anthrax Treated without Excision with Antianthrax Serum; Recovery.**—William Mitchell observed this case. The patient was a wool carder. When he first saw her, there was a pustule about one-fourth of an inch in diameter on the center of the upper eyelid. It was slightly pitted in the center where there was a small dark spot. Around its margin was a ring of indistinct vesicles. No pus was found in the vesicles. Local anthrax was diagnosed and antianthrax serum was injected subcutaneously. Microscopic examination of the fluid from the vesicles showed the characteristic anthrax bacilli in large numbers. In all, 100 c.c. of antitoxin was administered. Recovery was uneventful. However, the serum did not fulfill expectations so far as preventing necrosis was concerned. There is complete ectropion of the upper eyelid. All of the tissues superficial to the cartilage seem to be gone in the upper eyelid. The writer states that it is impossible to say what influences the serum had in bringing about recovery. No marked reaction could be noted after its use. However, he thinks from the favorable results obtained in Italy with the serum that one is justified in hoping that a remedy for this disease has at last been found. Large initial doses of 50 to 60 c.c. afford the best results. Serum treatment alone, without excision, when the anatomical situation of the lesion makes this possible, does not seem justifiable.

**An Experimental Inquiry into the Infection of Operative Wounds from the Skin, the Breath, and the Air.**—J. Rupert Collins has made various researches regarding these points. He believes that with an adequate use of the proper antiseptics in the proper order it is possible to obtain a degree of sterility of the skin which will stand the test of considerable maceration and friction. In order to attain this sterility, a prolonged careful scrubbing is necessary in order to remove the outside cuticle. The idea that by increasing the strength of antiseptics, the period required for disinfecting the hands can be shortened is erroneous. The best results are obtained by the use of a primary antiseptic which disintegrates rather than condenses the albumin of the skin, followed by an antiseptic which forms a hard, firm albuminate upon the surface of the skin. As to the air of the operating room, it is difficult to conceive any plan by which it can be made and kept absolutely sterile throughout an operation. However, many precautions to secure this end could be observed which are now neglected. The room should contain the minimum of furniture. As little moving about as possible should be indulged in. Air admitted to the room should be filtered through cotton-wool. All spectators should be kept outside of the room, observing the operation through a glass screen. All of those in the room should be clothed in a complete suit of sterilized material. As to the question of the surgeon's breath being a source of wound infection, the writer declares that it is only from solid particles discharged by a sputtering action that infection can occur from the breath. The infection carried by the breath in ordinary speech is doubtless small.

*Berliner klinische Wochenschrift, July 3, 1905.*

**The Treatment of Vaginismus.**—Budin says that he does not believe in either forcible dilatation under anesthesia or in incisions for the purpose of relieving this condition. He has used a method of gradual dilatation under local anesthesia with much success, and says that it has never failed him. For two or three days antiseptic vaginal douches, for example, of bichloride of mercury 1-4000, are prescribed. Then the vulva and the introitus are anointed with an ointment consisting of 1.5 g. of cocaine and 30 g. of vaseline. After ten to fifteen minutes the sensitiveness of the parts is greatly reduced, so that after a fresh application of the ointment the dilatation can be begun. The index finger can soon be introduced completely; it is withdrawn and a second finger is introduced with it, advancing very slowly and gently. Then Hegar dilators, warmed by immersion in hot water, are introduced. This is sufficient for the first session. The douches are repeated night and morning, and two days later, the mucous membrane is anesthetized in the same way and the dilatation is repeated with one or two fingers and the Hegar dilators. The douches are continued, and usually at the third treatment four fingers can be inserted. Sometimes only two sessions are required, sometimes four are necessary. The bougies are increased in size until the spasm of the muscles has disappeared, and the connection, preceded by the application of the cocaine ointment, can take place.

**Myomata and the Menopause.**—Winter says that the current belief has been that after the onset of the menopause uterine myomata become of less importance clinically and lose their dangerous attributes. He has used his material of 718 patients treated for myomata and including sixty-one cases in which the menopause had set in, for the purpose of studying this question. The results of the statistics in this list show that in the majority of cases the onset of the menopause entails cessation of the growth of the tumor and subsidence of the symptoms caused by it. The symptoms caused by myomata after the menopause are dependent on the not unusual expulsion of submucous growths, through their increased tendency to sarcomatous degeneration, and through hemorrhages sometimes arising from unknown causes. Sometimes myomata continue to grow after the menopause without any secondary degenerations; subserous growths are the most likely to do this, and interstitial ones the least. Operative interference for myomata after the menopause is not infrequently necessary; according to the author's figures, it is required in five per cent. of the cases. He accordingly concludes that the onset of the menopause does not involve the relief from the concomitants of myomata that is generally supposed.

*Munchener medizinische Wochenschrift, July 4, 1905.*

**The Spirochæta Pallida and Syphilis.**—Kiolemenoglou and Cube report the results of observations undertaken to determine the relationship of the spirochæta pallida to syphilis. In a series of syphilitic cases organisms corresponding to the spirochæta pallida were found, and control tests were made with non-luetic material. Unmistakable specimens of the spirochæta pallida were discovered in the balanitic secretion of an inflammatory phimosis (possible concealed chancre?), in the pus of a gonorrheal abscess of the Bartholinian gland of a patient suffering from specific leucoderma, in simple balanitis, in the pus of scrofulous abscesses, in the necrotic material of an ulcerating carcinoma, and in the secretion of pointed condylomata. Negative results were obtained in acute gonorrhea, the blood of syphilitics, in acne vulgaris, impetigo, and tuberculous sputum. The author feels that there is no doubt as to the identity of the organisms found in these cases, and in every instance the spirochæta refringens was also present in large numbers. In addition there were often found in the same field with the spirochæta pallida and refringens other forms of spirocheta which in many respects, such as size, morphology, and staining properties, differed from both of the former types. Some of these simulated the typical organisms so closely that it was practically impossible to differentiate them. The spirochætæ were always found most abundantly in situations in which there was decomposing secretion, so that it seems not unlikely that all the forms are simply saprophytes. At any rate it is decidedly premature to term the spirochæta pallida the causative agent of syphilis.

**A Case of Extrauterine Pregnancy with Extensive Deformity of the Fetus.**—Wiener describes this case which was that of a woman of twenty-eight who had had one normal labor. Between two and three months after cessation of menstruation she experienced sudden sharp abdominal pain which lasted about two weeks and was associated with a bloody discharge. Some months later on account of abdominal pain, vomiting, and very great increase in size of the abdomen an attempt was made to induce labor, but without effect. The patient was kept in bed, but her condition became steadily worse until when Wiener was called in at a period about corresponding to full term, she seemed almost moribund. She was in too

bad condition to move, so the laparotomy had to be done in her bed in a wretched farmhouse, but she made a good recovery, and some months later was able to do her work again. On opening the abdomen a great mass of adhesions was encountered, in the center of which was the spherical placenta and the full term macerated fetus. This had been subjected to tremendous compression against the placenta so that the parts were reduced to the thinness of paper. There was but little hemorrhage on removing the child and placenta, and the cavity remaining was drained with iodoform gauze. The author says that it is usually taken for granted that the occurrence of a pronounced bloody discharge indicates death of an extrauterine fetus, but that this was not the case in the present instance. Another interesting feature was the extreme degree of pressure which must have been brought to bear on the fetus and placenta by the abdominal walls in order to reduce them to the shapeless mass in which they were found.

**Aleppo Boil.**—Naab describes this affection, which is extremely common in the neighborhood of Bagdad, and especially along the course of the projected railway to the Persian Gulf. The disease is found all the year round, in cities more than in villages, and in all the regions of Asia Minor that are swampy or near river valleys. The author gives numerous reasons which have convinced him that the mosquito serves to transmit the infection, and he states that newcomers who have followed his advice to sleep only under mosquito nets have never been affected. He himself had ample opportunity to study the disease, as he contracted it during a journey with an infected compatriot, and in due time developed twenty-seven boils. After an incubation period of about a week a small itching nodule appears which gradually increases in size and at the end of about five months breaks open and begins to discharge serous fluid. The epidermis gradually breaks down, and for about five months longer there is an abundant purulent discharge accompanied by enlargement of the neighboring lymph nodes. The sores then slowly cicatrize, and in a little over eleven months are completely healed, and, owing to this fact, the disease is locally known as the "year boil." Of the various plans of treatment tried by the author the application of methyl violet in eight per cent. alcohol seemed to give the best results. One attack confers immunity.

*Deutsche medizinische Wochenschrift, July 6, 1905.*

**The Diagnosis and Treatment of Chronic Perityphlitis.**—Boas, in discussing this subject, endeavors to show that the determination of the indications for operation as well as the diagnosis in these cases falls entirely within the province of internal medicine. He admits that in nearly all cases the hope of effecting an absolute cure by medical measures is slight, but he considers that under certain conditions, as in old age, operation may be dispensed with. He points out that the American classification of chronic appendicitis into two forms, the recurrent and the relapsing, has not met with the recognition on the part of the Continental surgeons that it deserves, and he urges its adoption, as the prognosis is quite different in the two types. Speaking with the reservations necessary in dealing with so uncertain a disease, he expresses the belief that the cases which begin as the chronic form, that is without any initial acute attack, always remain chronic, and that acute exacerbations with high temperature and the symptoms of perforation are the exception. The diagnosis of these chronic cases is often extremely difficult and in many cases the presence of cutaneous hyperesthesia limited to the region of the appendix is a valuable though not an infallible sign. Boas does not believe it is very often possible to be sure of palpating the appendix as there are too many chances of mistaking other structures for it. A useful measure is to make continuous temperature observations, comparing the temperatures obtained by rectum and in the axilla. If a difference between the two of more than .5° C. is repeatedly found, it speaks in favor of an inflammatory process in the pelvic organs.

**The Treatment of Incarcerated Hernia.**—Brix says that the country practitioner who is obliged to do his work without the conveniences and assistance possible in the city is often forced to struggle with an obstinate incarcerated hernia, and finds his suggestions for operative intervention met with refusal. Under such conditions, after fruitlessly exhausting every device he could think of, he thoroughly froze the surface of the tumor with ethyl chloride spray, and then found that the volume of the mass had diminished so much that reduction could be accomplished with great ease. On numerous subsequent occasions he found the plan equally serviceable and he warmly commends it in such cases. The cold produced by the evaporation of the ethyl chloride is so intense that great vasoconstriction results both in the constricting ring and in the incarcerated mass, so that the former becomes larger and the latter diminished in mass, whereby reduction becomes easily possible.

*French and Italian Journals.*

**Treatment of Bronchial Dilatation by Pneumotomy.**—Tuffier presented a report concerning an observation made by Antipas in relation to a child four years old who showed all of the signs of a suppurating cavity at the base of the lung, with vomiting. Pneumotomy showed that the suppurating cavity corresponded neither in dimension nor in position to the lesions diagnosed by auscultation. The cavity was small, of the size of a nut, and consisted of a bronchial dilatation. Antipas drained this cavity. A permanent fistula was established and the young patient finally succumbed to an acute pneumonia. Apropos of this case, Tuffier advocates pneumotomy in cases of bronchitic ectasia. He declares that he would be disposed in future cases to have recourse to a thoracoplasty which would favor pulmonary retraction and the spontaneous obliteration of bronchitic dilatation.—*Gazette des Hôpitaux Civils et Militaires*, July 4, 1905.

**Multiple and Symmetrical Osteogenic Exostoses.**—Teissier and Deneachau had under their care a child who showed multiple and symmetrical osteogenic exostoses. One of these growths was situated on the upper third of the right humerus and was the size of a large orange. By the *x*-ray, its ossification was seen to be almost perfect. The interesting point of this case was that in relation to heredity, for the father has similar exostoses and a congenital malformation on the left ulna. In two other children there were also malformations; one showed exostoses and the other scoliosis. Finally, the paternal grandfather had similar tumors on the upper and lower extremities; these were congenital and were well known to all the inhabitants of the village. The affection was hereditary and has been noted in three generations.—*Le Bulletin Médical*, July 8, 1905.

**Sleeping Sickness in a White Man.**—Sicard and Moutier report the case of a man twenty-eight years of age who was attacked by the sleeping sickness. The affection had been contracted two years before in Gambia, a country in which trypanosomiasis is very common. The beginning of the illness was marked by headache, lassitude, and generalized asthenia. Later, partial contractures and epileptiform crises developed, followed by torpor. For eight months the man has slept heavily for from ten to twenty hours a day. Fever has also been present. The patient suffers from incontinence of urine and feces and has a sacral eschar. The trypanosoma has not been found either in the blood or in the cerebrospinal fluid; but in the white man the investigation of these fluids does not always meet with positive results.—*Journal des Praticiens*, July 8, 1905.

**Gonorrheal Endocarditis; Determination of the Gonococcus in the Blood During Life and in a Valvular Vegetation After Death.**—Widal and Faure-Beaulieu report this case. The patient was a boy seventeen years of age, suffering from aortic insufficiency due to an old attack of rheumatism which had followed gonorrheal infection. Thirty-four days after the beginning of the gonorrhea, the symptoms of an acute endocarditis developed. A second murmur became audible. Fever was intermittent. Embolism of the left popliteal artery supervened. The patient died twenty-four days after the beginning of the endocarditis. The gonococcus had been cultivated from the blood. At autopsy, besides the old lesion of aortic insufficiency a recent vegetation was found on the mitral valve, and microscopical examination revealed in it the presence of the gonococcus. This double determination of the gonococcus—in the blood during life, and in the valvular vegetation after death, proved the gonorrheal nature of the endocarditis and once more the reality of gonorrheal septicemia.—*Gazette des Hôpitaux Civils et Militaires*, July 4, 1905.

**Structure of the Normally Inserted Placenta in Cases of Premature Detachment.**—Guido Biancardi has examined the placenta in several cases of premature separation and gives us the results. (1) In some cases of early detachment of a normally inserted placenta, without any sufficient cause conditions of structure exist which may account for the detachment. (2) Such conditions are primary fatty degeneration of the placenta, associated with inflammatory lesions and secondary extravasations of blood, and alterations of villi, even the fetal portion taking part in the changes. The cause of these alterations is an endometritis continuing into pregnancy. (3) There is nothing special about these alterations differing from those arising from other pathological conditions of the placenta. (4) The location, extension, and nature of the lesions may account for some peculiarities in the symptomatology of the case.—*Annali di Ostetricia e Ginecologia*, May, 1905.

# Book Reviews.

Die Chronische Gonorrhoe der männlichen Harnröhre und ihre Komplicationen, von Prof. Dr. F. M. Oberländer und Prof. Dr. A. Kollmann. Parts II. and III. Liepzig: Georg Thieme, 1905.

We reviewed Part I. of this work about three years ago. Like its predecessor, the volume containing these concluding parts is essentially written for the busy practitioner, or for him who struggles with the obstinacies of chronic gonorrhea. Coming as this book does from the originator (Oberländer) of the urethroscopic method of dealing with this disease, and from him who further developed the dilatation method (Kollmann), it carries the weight of authority. The authors, with characteristic fairness, do not condemn the means employed by others; indeed, they emphasize on page 3 of the introductory to Part II. that "the good results obtained by a physician with his own instruments and methods naturally depend in part upon his being specially drilled in their use." As regards their own methods and instruments, the authors are especially strict. They freely discuss the apparently brilliant results in light cases, which seemed to be severe, and refrain from taking credit for the cure in such patients. They again lay special stress upon the diagnostic value of visual inspection of the urethra in chronic gonorrhea. They say in this connection: "Urethroscopy, with effective, practical instruments, is the best and safest aid to diagnosis." They show that, while the technique of urethroscopy is very readily acquired, adequate recognition of diseased appearances demands much practice. The question whether chronic gonorrhea in the male can be successfully treated without instrumentation is one of the propositions that still comes to the specialist. Oberländer and Kollmann show that even trifling cases demand instrumentation for their diagnosis; that with aseptic precautions, which they fully detail, cautious instrumentation is never dangerous, and that without instrumentation the conditions which underlie chronic gonorrhea of the male urethra are not curable. The rare exceptions hereto are shown to be cases in which a true chronic gonorrhea was not present. Even in these, repeated introduction of instruments is inevitable to confirm complete cure. In connection with this problem, the circumstances and conditions are detailed which temporarily prohibit instrumentation. As a principle for success, Oberländer and Kollman demonstrate that "in the treatment of chronic gonorrhea it is the highest art to arrest instrumental treatment at the proper time and await the outcome. Oftentimes surprising results are the consequence." The thoroughness of the work is not made evident by the preceding meager excerpts. Throughout it is concisely written, serving as a book of reference not only for the specialist but for the general practitioner as well. The only unfavorable criticism that would be just meets its field in the index, which, while occupying nine pages, is inadequate for the nearly 700 pages of text of the three parts of this admirable work.

It will certainly be desirable if the authors give heed to this necessity in future editions, which are sure to be demanded. The profession has waited long for the parts now published; it will agree, on reading, studying, and putting to practical use the knowledge contained, that, though the delay has been long, the volume has been well worth waiting for.

The Doctor's Window. Poems by the Doctor, for the Doctor, and about the Doctor. Edited by Ina Russelle Warren. With an Introduction by William Pepper, A.M., M.D. Chicago, Akron, O., New York: The Saalfield Publishing Co., 1904.

This is Volume V. of The Doctor's Recreation Series, edited by Charles Wells Moulton. It is a well arranged and most judiciously selected anthology of verse written by or about the medical man, first published in 1897, at which time the introduction by the late Dr. Pepper was written. The book derives its title from the first selection, the poem of that name (on a little gleam of sunshine in a dismal back yard) by Austin Dolson, which is, of course, familiar to most readers, whether medical or lay. There are other selections by Oliver Wendell Holmes, James Whitcomb Riley, S. Baring-Gould, John G. Saxe, Locker-Lampson, Whittier, Walt Whitman, Will Carleton, and Eugene Field; by Byron, Ben Johnson, and Chaucer; and, among contemporary medical men, by Weir Mitchell, Andrew H. Smith, Edward D. Freeman, William Tod Helmuth, Samuel W. Kelley, Frederick Peterson, John C. Hemmeter, E. B. Ward, and a number of others. The selections, some of which are familiar, but many new, are very good, and those written by physicians are by no means the least entertaining. We wish more could have been taken from medical writers, for these are usually hidden in the pages of local journals or medical magazines, where they will be lost for all time unless framed in some such collection as this. There are many such that have found no abiding place here, though they are well worthy of it, but another volume would be needed to hold them all. There is enough here to give the reader many a pleasant half-hour when he is too tired with the work of the day to read anything of a serious nature or even a novel calling for any connected thought. The printing and binding are excellently done, uniform with the other volumes of this interesting series.

Endoscopie de L'Urètre et de la Vessie. Par le Dr. Georges Luys, Ancien Assistant du Service des Voies Urinaires a l'Hôpital Lariboisière; Ancien Aide d'Anatomie à la Faculté de Médecine de Paris. Préface par le Dr. Henri Hartmann, Professor agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Lariboisière. Paris: Masson et Cie., 1905.

This work on urethral and vesical endoscopy is the first of its kind to appear in France, though many such have been published in the German and English languages. The author, whose work on the separation of the urines from the two kidneys has shown him to possess an inventive faculty of superior order, here treats of the importance of urethroscopy, especially in the diagnosis and treatment of chronic affections of this canal, and describes the instruments for this purpose which he has perfected. The technique of urethroscopy and cystoscopy is described in very clear and simple terms, and the text is elucidated with a number of excellent illustrations. Dr. Luys prefers direct cystoscopy, which presents many advantages, he believes, over other methods. The author is one of the most original of the French workers in diseases of the urinary apparatus, and his book is one that should be in the hands of every student and practitioner of this rapidly advancing specialty. It forms a companion volume to the work on "La Séparation de l'Urine des deux Reins," by the same author, which was reviewed in these columns about a year ago.

Le Tube Contourné du Rein: Etude histologique anatomo-pathologique expèrimentale. Par Le Docteur Francis Rathery, Interne médaille d'or des hôpitaux de Paris. Paris: G. Steinheil, 1905.

In this volume the convoluted tubules of the kidney receive the attention of the author. The book represents a considerable amount of work in the pathological laboratory; it contains seven chapters and concludes with a résumé of numerous experiments and a bibliography. The first chapter contains the details of technique; the second and third deal, respectively, with the convoluted tubule in animals and in man; chapter four treats of lesions produced experimentally; the fifth discusses the pathological anatomy of the tubules in man; the sixth is devoted to the subject of nephrotoxins; and the last chapter discusses the bearing of heredity on renal disease. The chapter on nephrotoxins is the longest and most important of the subjects here presented.

Practical Dietetics. With Special Reference to Diet in Disease. By W. Gilman Thompson, M.D. Professor of Medicine in the Cornell University Medical College in New York City, Visiting Physician to the Presbyterian and Bellevue Hospitals. Third Edition, enlarged and thoroughly revised. New York and London: D. Appleton and Company, 1905.

As this book is so well known, it is hardly necessary to do more than call attention to the appearance of a new edition. The volume has been considerably enlarged, especially, the author says, in the sections dealing with the analysis of gastric contents, intestinal autointoxication, milk as a food, diabetes, and in the portions concerned with the dietetic treatment of disease. Reference to these topics proves that they are well in accord with modern views, and that the new matter is worthy of the old. The subject of feeding both in health and disease is so vital a one that it is rather surprising that more books are not written on it. The plates deserve but little praise, with the exception, possibly, of those numbered III and VI, and they call to mind the young lady in Calverley's poem, of whom it is said that "she does not seem to serve a useful end, and certainly she is not beautiful." Maranta is misspelled both on the plate depicting its starch grains and in the list of illustrations, which latter has not been revised to correspond to the paging of the new edition.

The Rôle of Modern Dietetics in the Causation of Disease. By J. Sim Wallace, M.D., D.Sc., L.D.S. Hon. Dental Surgeon West End Hospital for Nervous Diseases and Assistant Dental Surgeon National Dental Hospital, W. London: Baillière, Tindall & Cox, 1905.

The volume before us is a collection of published and unpublished essays on subjects which are of common interest to the medical and dental practitioner. The author shows the influence of bad teeth, insufficient mastication, soft foods, nasal obstruction, etc., on the causation of disease. Some "speculations and suggestions" in the final chapter are excellent food for thought, and well worthy of digestion.

## AMERICAN MEDICAL ASSOCIATION.

*Fifty-Sixth Annual Meeting, Held in Portland, Ore., July 11, 12, 13, and 14, 1905.*

(Special Report to the MEDICAL RECORD.)

(*Continued from page 162.*)

### SECTION ON MEDICINE.

*Second Day—Wednesday, July 12.*

**General Considerations on the Pathology of the Kidney.**—Dr. W. T. COUNCILMAN of Boston presented this communication as the opening paper of a "Symposium on Nephritis." In the absence of the author the paper was discussed, in brief, by Dr. RICHARD C. CABOT of Boston. He said that cases of nephritis or renal trouble which were manifested by albumin and casts were at times moderately severe or mild cases, but not of the severest form. For instance, one might meet with occasional hemorrhagic infarctions, in which a portion of the kidney was thrown out of function, and yet no albumin or casts were seen. In some cases in which the functions of the kidney was partly destroyed no albumin or casts would appear. It seemed to him that in the moderately severe cases we got these clinical manifestations. In the relation of edema and nephritis, he said that Dr. Councilman would have shown that the association between them was unreliable. The classification of the forms of nephritis he considered to be very important and was practically the same that he had presented in former communications on this subject. He divided nephritis according as the glomeruli showed or did not show important changes. Amyloid nephritis was not classified under these heads. Out of thirty-six autopsies there was only one case of amyloid nephritis which was accompanied by cardiac hypertrophy; while out of eighty cases of chronic interstitial nephritis, seventy-six showed marked hypertrophy of the heart. In the glomerular cases, the association of hypertrophy of the heart was regular and constant. He emphasized the fact that kidney disease was always a part and never a whole; it was one branch of an infectious process, or toxic process, widespread in the organism in which the kidney forms only one part.

**Albuminuria in Nephritis and Bright's Disease.**—Dr. ALFRED STENGEL of Philadelphia emphasized the necessity of distinguishing nephritis in the pathological sense from nephritis (Bright's disease) in the clinical sense. He reported 581 cases, among which there were 51 cases of undoubted clinical nephritis, or Bright's disease, exclusive of chronic interstitial nephritis. In all there was a constant and more or less uniform albuminuria. In 74 cases of arteriosclerosis there was albuminuria, not always constant, without casts in 16, with casts in 58. A number of these properly fell under the name of chronic interstitial nephritis. In 187 cases there was occasional albuminuria in association with acute infectious diseases, gout, diabetes, tuberculosis, and syphilis, cystitis, pyelitis, cardiac disease, movable kidney, gallstones, etc. In 41 cases there was occasional albuminuria; in 215 cases there was no albumin at any time; and in 11 cases casts were found without albumin. Among 154 cases of cardiovascular disease, albubin or casts or both occurred in 81, and no albumin or casts in 73. In conclusion he said that the purpose of his paper had been primarily to direct attention to the fact the albuminuria and the presence of tube casts were extremely common occurrences in various general diseases, and that though they might indicate in a sense inflammatory conditions of the kidney, such were of pathological rather than clinical significance, unless the albuminuria was considerable and more or less constant. The nature of the accompanying tube casts should not be too greatly relied upon in determining the seriousness of the renal lesion. It should be remembered that the modern method of centrifugation and the consequent examination of quite fresh urine increased the likelihood of our discovering casts; and there was no sharp line of distinction between the comparatively insignificant cylindrical of the mildest grades of renal irritation, and the definite hyaline casts of more decided disease.

**Cylindruria.**—Dr. CHARLES P. EMERSON of Baltimore briefly discussed the formation and significance of casts, especially the hyaline, with a classification of this group. He also presented a study of all cases that occurred in the Johns Hopkins Hospital.

**The Relation of Kidney Conditions to Puerperal Eclampsia.**—Dr. PHILIP KING BROWN of San Francisco said that sources of his information for this paper were statistics from hospitals and private sources on eclampsia and kidney conditions, the literature on eclampsia and metabolism, personal observation on urea elimination in pathological conditions of pregnancy, and experiments on the muscular irritability of pregnant and non-pregnant animals. He offered the following summary: (1) Albumin was present in fully 80 per cent. of normal pregnancies. (2) Albumin and casts were found in 30 per cent. at least of all pregnancies. (3) There was no reason to suppose that the renal condition thus revealed was the cause of eclampsia. (4) That there was some connection, however, between the albuminuria and the extra renal cause of the eclampsia, was likely in view of the nearly constant association of the two. (5) It has been shown that neither any normal end product nor any known intermediary product of metabolism was the cause of eclampsia. (6) It was reasonable to suppose that deficient thyroid activity played a part at least in some of the cases of eclampsia. (7) There were probably several causal factors to the separate or concomitant action of which eclampsia seemed to be due. (8) The most significant experimental work done up to this time pointed to the fact that in the placenta was found the toxic substances which probably were responsible for eclampsia. (9) There was good evidence that these same substances were in all probability the causes of the headaches, edema, abdominal pain, and particularly the albuminuria present in the non-eclamptic and non-nephritic cases. (10) The nervous systems of pregnant women were in an abnormally sensitive condition. Their blood had been shown to be abnormally toxic. There was no conclusive proof of an increased or diminished toxicity of the urine. (11) My own experiments have shown that the muscles of the pregnant guinea pigs could be thrown into convlusion more easily than those of non-pregnant animals.

**The Dietetic Treatment of Nephritis.**—Dr. F. C. SHATTUCK of Boston presented this communication and said that the leading principles pertaining to the dietetic treatment of nephritis might be stated somewhat as follows: (1) Such control as we might have to-day of nephritis lay in diet and mode of life rather than in drugs. (2) Such drugs as were useful were so in their effect on the general organism or on the heart rather than on the kidneys directly. (3) In all cases of nephritis our broad aim was to spare the kidneys unnecessary work, not forgetting that the urinary was but one of the systems which comprised the body. (4) In acute nephritis, as well as in acute exacerbations of the chronic forms Doctors Diet and Quiet should work together. Starvation for a few days proportionate to the intensity of the process and the strength of the patient, was the keynote of the dietetic management. (5) In the chronic forms we sought to lengthen and lighten life, an aim often largely within our power of attainment. Especially in the contracted form of kidney disease many years of life, much of the happiness which comes from achievement, days and nights of comfort might hinge on our skill in adapting sound principles to the particular case and in securing the cooperation of the patient in carying out the same persistently, not spasmodically. Dietary restriction should be in the main quantitative rather than qualitative. Alcohol in moderation was

not necessarily a poison, and might be an aid to digestion. (6) The excess of proteid, not proteid in itself, was harmful to the chronically sick kidney. (7) A varied was more likely than a monotonous diet to promote the manufacture of good blood and thus to promote good nutrition of the body in general and of the myocardium in particular. (8) The amount of albumin was in itself no guide as to the extent of dietary restrictions.

Dr. John A. Witherspoon of Nashville, Tenn., said that he had been very much impressed with the reparative and recuperative powers of the kidneys for a number of years. He believed that men were in too big a hurry and made their diagnoses too quickly. Many of the prognostications offered would be changed if the cases were watched for a sufficient length of time. Medicine played but a small part in the treatment of disease, and especially in that of kidney disease, and more attention should be paid to diet and general management.

Dr. W. Ophüls of San Francisco referred to certain experiments carried on to determine the relation between albuminuria and nephritis, the kidneys being examined at autopsy. He showed that a large amount of albumin and casts of any kind might be present in the urine and still no lesions noted, either microscopically or macroscopically, beyond congestion, which could give rise to the conditions found.

Dr. L. Duncan Bulkley of New York described his own acute attacks of nephritis when his urine was black as coffee, thick and solid; he cured himself by dieting upon milk, taking it at the body temperature. He emphasized the importance of knowing just what the kidneys were doing day by day, and the frequent testing of the urine.

Dr. G. W. McCaskey of Fort Wayne, Ind., said that a few years ago he was impressed with the fact that physicians were underfeeding their patients and he began giving an ordinary diet. He insisted upon more attention being paid to the condition of the gastrointestinal tract because he was a believer in a cause of nephritis being the toxins which were absorbed therefrom.

Dr. Woods Hutchinson of Portland, Oregon, did not believe that Bright's disease was primarily a disease of the kidneys, but often the result of an arteriosclerosis or fibrosis due to the action of toxins, and the kidneys suffered from their attempts at elimination of these. Milk as a food in nephritis was harmful because it swarmed with bacteria. Any diet which diminished the amount of intoxication in the tissues and built up the patient's strength was the one best fitted in cases of nephritis.

Dr. A. P. Francine of Philadelphia spoke of the work done at the Phipps Institute. In a series of 53 cases of pulmonary tuberculosis only one kidney was found to be normal, and in 34 of them evidences of tuberculosis were found.

Dr. James J. Walsh of New York emphasized the importance of an early diagnosis of nephritis and said that attention should be directed to such kidney lesions by the high tension pulse, accentuated second heart sound, fluttering sensations referred to the heart, with certain digestive disturbances, etc.

Dr. Frank Billings of Chicago spoke of the misinterpretation of casts and albumin in the urine and said that many individuals died of apoplexy when they were the subjects of Bright's disease and with the urine filled with albumin and casts. Cardiovascular and degenerative changes in other parts of the body might give expression in the urine.

Dr. John H. Musser of Philadelphia emphasized the importance of making complete examinations of the urine in order that one might lay down proper dietetic treatment, make a study of the nitrogen output, and a study of the elements found that were secondary to putrefactive changes occurring within the intestinal tract.

Dr. H. M. Fussell of Philadelphia sounded a word of warning by saying that if they said that albumin and casts occurring in the urine did not mean a nephritis, the general practitioner might say, Why examine the urine at all? It was of the greatest importance that the urine be carefully examined and in a routine manner in order to determine the presence of these danger signals.

Dr. L. Leroy of Nashville, Tenn., believed that the future classification of nephritis would be based upon the etiology. He said he had found many kidneys doing functional work well and yet with certain of the pyramids the seats of advanced degenerations. He advocated the use of boiled meats which were rid of their extractives which had such an irritating effect upon the kidneys.

Dr. J. A. Lichty of Pittsburg called attention to the use of the sphygmograph in estimating the blood pressure, and thought that more attention should be made to its use in determining the existence of nephritis.

**Symptoms, Diagnosis, and Prognosis of Amebiasis in the Tropics.**—Dr. W. E. Musgrave of Manila, P. I., presented as the opening paper of a symposium on animal parasites and tropical disease a very lengthy communication on this subject. He discussed the subject under the following clinical divisions: Latent and masked infections, mild and moderately severe cases, severe cases including gangrenous and diphtheritic ones, infection in the children and in the aged. The clinical forms changed from the one to the other and might do so several times during the course of the disease in the same patient. The amebic process in all was essentially chronic, but acute symptoms from concurrent or secondary infection by other agents were frequently seen. Constipation was a very prevalent condition in the tropics, particularly among women, and, as might be inferred, might frequently mask amebic infection in the early stages, and the latent and less active forms until irreparable damage might have been done to the colon. The mild and moderately severe cases formed the great majority of those seen in Manila at the present time. A particularly noticeable thing, both in children and in the aged, as well as in natives of the Philippine Islands, was the great relative infrequency of liver abscess. He had not seen a case of liver abscess in more than one thousand clinical cases, and one hundred autopsies of natives of the Philippine Islands. The most important clinical manifestations in a question of diagnosis were the bowel evacuations, particularly their odor, and the presence or absence of blood. Abdominal soreness increased on pressure, and extending particularly along the colon, was most common and, taken singly, was one of the most valuable symptoms. Its diagnostic importance was greatest when so-called "indigestion" was quite common. Loss of weight, especially in the presence of a good appetite, was quite important, and was the best guide to the progress being made by the infection. Neither one nor all of these symptoms taken together were sufficient for an absolute diagnosis; but when taken together, in cases where careful palpation revealed a thickened, tender colon in places where it might be felt, this made the nearest approach to a sure diagnosis, without microscopical examination of the feces. Waiting for bloody mucous stools to appear before making a diagnosis and instituting treatment was responsible for a large percentage of the present mortality from the disease in Manila.

**The Pathology of Intestinal Amebiasis.**—He offered the following conclusions: (1) Intestinal amebiasis was a peculiarly ulcerative condition of the intestine caused by amœba coli (Losch) usually confined to the large intestine, though occasionally (7 in 200 cases) the ileum was affected and more often (14 in 20 cases) the appendix was involved. (2) In the majority of cases the condition affected the entire bowel (159 in 200 cases), though it might be limited to one or more portions, most commonly the cecum and ascending colon (23 in 200 cases). (3) The ulcers showed a tendency to be undermined, due to the lack of resistance on the part of the submucous layer of the bowel. (4) The organisms might enter the blood vessels very early in the disease and might be transported to the submucosa without lesions of the muscularis mucosa.

(5) The disease is a subacute chronic inflammatory process, as shown by the character of the exudate and infiltration, by the early formation of granulation tissue and by the absence of leucocytic infiltration. (6) Complete healing might be accomplished, or a condition of chronic atrophic enteritis or chronic catarrh might persist, known as sprue or psilosis.

**The Mode of Infection in Uncinariasis.**—Dr. CLAUDE A. SMITH of Atlanta, Ga., gave a lantern slide demonstration showing the natural and artificial conditions under which the larvæ of the uncinaria developed. He also referred to the chances of the larvæ gaining access to the human body, and the seasons of the year and conditions under which this was likely to occur.

*Third Day—Thursday, July 13.*

**Recent Advances in the Physiology of Human Nutrition.** Dr. FRANK BILLINGS of Chicago said there was no subject of greater physiological importance or of greater moment for the welfare of the human race than the subject of nutrition. How best to maintain the body in a condition of health and strength, how to establish the highest degree of efficiency, both physical and mental, with the least expenditure of energy, were questions in nutrition which every enlightened individual should know; yet even the expert physiologist was uncertain as to what constituted a proper dietary for different conditions of life and varying degrees of activity. We heard divergent views regarding the needs of the body as to the extent and character of the food requirements, contradictory statements as to the relative merits of animal and vegetable foods. There was a lack of agreement regarding many of the fundamental questions that constantly arose in any consideration of the nutrition of the body. Especially was this true regarding the so-called dietary standards, or the food requirements of the healthy adult. Certain general standards had been adopted, but one was forced to the conclusion that these standards had an uncertain value when one saw instances of individuals living in apparent health under a dietary not at all in harmony with the recognized standards. We needed definite knowledge of the physiological necessities of the body for proteid or albuminous foods, those foods which we are accustomed to speak of as essential, or absolutely requisite for life. Have we, through years and generations, established the habit of taking undue quantities of proteid food which might be largely in excess of the physiological requirements of the body? If so, then we had to consider the possibility that an excess of daily food might be more or less responsible for many diseased conditions, which might be obviated by a more careful observance of the nutritional needs of the body. The definite information as to what the real necessities of the body for proteid foods had recently been carefully studied by Russell H. Chittenden, Director of the Sheffield Scientific School of Yale University, and Professor of Physiological Chemistry, in a series of experiments, which had been published in book form under the title of "Physiological Economy in Nutrition." The result of Chittenden's experiments, with the experiments and conclusions of Professor Pawlaw upon the work of the digestive glands, and the "Theory of Protein Metabolism," by Otto Folin, of McLean Hospital for the Insane, Waverly, Mass., afforded a clearer view of the physiology of nutrition than we had hitherto possessed.

**Methods, Value, and Limitations of the Knowledge of the Gastric Contents.**—Dr. GEORGE DOCK of Ann Arbor, Mich., believed that instrumental and laboratory examinations with reference to the stomach were unduly neglected in practice, and many failed to make such examinations because they thought the passage of the stomach tube was difficult. In his experience this was not so. Training and practical experience were necessary for its success. He said the absence of hydrochloric acid in cancer was frequent, but cancer might be present with hydrochloric acid preserved for a long time, and even in excess of the normal amount. But such exceptions and contradictions occurred in all branches of diagnosis, and they should teach us to discover other details. He said he could cite a number of cases in which there was not an excessive secretion by hydrochloric acid in gastric ulcer. Single or a few examinations were misleading. The value of estimations of hydrochloric acid he believed to be greatest in the functional diseases of the stomach, or rather cases in which the stomach functions were altered, without gross organic disease primarily in that organ, though there might be functional or organic diseases in other organs that might have a part in the production of the gastric anomaly. Often it occurred with no gastric symptoms, or with trifling ones, but with distant symptoms. In functional diseases the greatest help was often derived from frequent estimations of hydrochloric acid under various kinds of dietetic and other treatment. There was still room for further investigation in the methods of gastric chemical examination. Günzberg's reagent he used largely. To determine the amount of hydrochloric acid dimethyl-amidoazo-benzole was most satisfactory. For the total acidity the phenolphthalein reaction was used. Test for the combined hydrochloric acid was not necessary, as a rule. Of abnormal or pathological acids, lactic was the only one requiring chemical tests, for acetic acid or butyric acid often occurred in large quantities, and could be detected by the odor. The determination of pepsin was not necessary in ordinary work, since it was rarely absent when hydrochloric acid was present in sufficient quantities. The digestive functions could easily be shown by the biuret test.

**Non-gastric Diseases Presenting Gastric Symptoms.**—Dr. J. H. MUSSER of Philadelphia discussed the symptoms of gastric diseases simulating various diseases of the stomach in certain infections, in intoxications, in organic disease of the brain and spinal cord, in diseases of the heart and blood-vessels, of the lungs and the kidneys. He also considered the significance of pain, vomiting, modifications of secretion, etc., in non-gastric disease.

**Food Stagnation from All Causes.**—Dr. CHARLES G. STOCKTON of Buffalo said that food stagnation was one of the most important of the gastric disturbances. The local symptoms were distress and sense of weight, sometimes pain, together with eructations of gas, regurgitation of the stomach contents, and often vomiting. Constitutionally there were usually found evidences of autointoxication and starvation. He divided the cases into two classes—first, those in which stagnation resulted from depression of the motor functions of the stomach, without the presence of any actual obstruction; second, those in which there was actual obstruction to the overflow of stomach contents, regardless of the kinetic energy of the gastric walls. After considering the causes of these two classes of cases, he said that the diagnosis was not difficult, and that it might be suspected when patients complained of eructations of food taken a long time previously. It could be demonstrated only by the use of the stomach tube. The motor power might be assisted by certain mechanical measures, especially by skillful massage over the region of the stomach, by trunk rotation and flexion, and by the alternate hot and cold douche over the epigastrium, and by external and internal faradization. Benefit undoubtedly followed the use of the simple carminatives, bitter infusions, and temporarily the diffusible stimulants. Failure or success depended more upon general management of the patient, upon proper rest, exercise, recreation, diet, mental state, etc., than upon the mere local treatment of the stomach. In cases of motor insufficiency depending upon spasm of the pylorus from over-irritability of tissue, whether from hyperchlorhydria, hyperesthesia, or simple erosion of the pyloric mucosa, surgery should not be considered. The proper treatment consisted in lowering the acidity of the gastric secretions, soothing the gastric mucosa, and the selection of an unstimulating, liquid or very soft diet, which was free from all irritating particles. Lavage, followed by soothing lavements of the mucous membrane, was of great assistance. He emphasized the fact that a stomach

on which the gastroenterostomy had been performed was by no manner of means as good as a normal stomach. But if an ulcer continued to give trouble, if pain and spasm frequently occurred, he recommended pyloroplasty, if the ulcer could be safely excised, otherwise gastroenterostomy. In benign hypertrophy of the pylorus, without ulcer, he advised operation, preferably pyloroplasty.

Drs. G. W. McCaskey of Ft. Wayne, Ind., Morris Manges of New York, J. S. Miller of Chicago, J. M. Anders of Philadelphia, F. C. Shattuck of Boston, J. L. Bond of Ukiah Cal., James J. Walsh of New York, J. A. Lichty of Pittsburg, C. M. Cooper of San Francisco, Norman Bridges of Los Angeles, discussed these papers.

**A Type of Tuberculosis on the North Pacific Coast.**—Dr. Woods Hutchinson of Portland, Ore., referred to a type of tuberculosis on the North Pacific coast, particularly in Oregon, Washington, Idaho, and Montana, which was marked by the following characteristics: A remarkably rapid course, running from three to nine months; a weak and rapid pulse, ranging from 105 to 145; a wide range of daily temperature, more subnormal depression than elevation, the morning temperature not infrequently being 95°, the afternoon, from 101° to 103°; rapid infiltration and boad-like consolidation beginning in both apices, and extending toward the base with almost total absence of cavitation; if cavities were present, they were small and scattered; there was marked infrequency of pulmonary hemorrhage; there was slightness or absence of cough and other symptoms of pulmonary irritation. This type of tuberculosis was most frequent in the native born. He asked if this was a hitherto undescribed type, and was it due to climate, or to some special development of unusual virulence in the bacillus, or was the lung, or heart chiefly at fault in tuberculosis, or was oxidation deficient or excessive in the consumptive? He then gave the rationale of open-air treatment.

Drs. Wm. F. Cheney of San Francisco, J. S. Miller of Chicago, Norman Bridge of Los Angeles, Philip K. Brown of San Francisco, Wm. Ophulus of San Francisco, M. C. Robbins of Spokane, D. E. Osborne of St. Helens, California, Herbert C. Moffitt of San Francisco, discussed this paper.

**Coccidioidal Granuloma.**—Dr. W. Ophuls of San Francisco, Cal., read this paper. He said that they had in California a peculiar form of oidiomycosis of which so far no case had been described in people who had not been in his State except the very first case of this form of infection which was observed by Wernicke in Buenos Ayres, and later and more accurately described by Posadas. One paper established fully the morphology of the parasite in the tissues and the nature of the lesions which it produced, but at that time, 1894, the organism was looked upon as a protozoon. This view of the animal nature of the parasite proved to be erroneous, in the course of the examination of a new case of this disease which occurred in 1900, when it became apparent that the parasite could be cultivated and developed in the cultures in the form of a mould-like growth. It probably belonged to the oidia, and he, therefore, proposed the name *Oidium coccidioides*. The parasite in coccidioidal granuloma differed from the various fungi described in blastomycetic dermatitis, first by the absence of budding during its development in the tissues, second by its mutiplication by endosporulation, third by certain differences in its growth on artificial culture media. He said there were now on record 10 cases of coccidioidal granuloma to which he could add 3 new cases, making 13 in all. In one of the cases reported a very remarkable feature was that tubercle bacilli and no other parasites were found in the adrenals, whereas no tubercle bacilli, but many oidia could be demonstrated in the meninges. A great variety of lesions were produced by the parasite, and a great variety of organs were affected, and the clinical symptoms, of course, depended entirely upon the localization and intensity of the disease. So far no typical clinical picture could be given, but, in some cases, there was a striking resemblance to tuberculosis. The most characteristic manifestations of this disease were nodules consisting of granulation tissue at various stages of development, but in addition suppurative processes usually of a chronic character. The infection with *Oidium coccidioidcs*, therefore, produced either submiliary, miliary, or larger nodules, which resembled tuberculosis very closely. These nodules might caseate. Later the caseous material might liquify and cavities containing pus-like material might be produced in this way. He described the cutaneous lesions which seemed to have been the primary seat of infection in some of the cases. The disease seemed to be almost limited to California. The cases had been found at considerable intervals in San Francisco, in people coming from the country who had no apparent relation to one another. From what was known of the cultivation experiments, it seemed quite possible that the oidium occurred in nature, and caused infection only occasionally. It had been suggested that the trouble might be primarily an animal disease, and only occasionally transmitted to human beings, but it had not been as yet possible to adduce any evidence in support of this theory. The resemblance of the disease to tuberculosis was so great clinically and anatomically that the true nature of the cases was recognized only when a careful microscopical examination was made of the diseased tissues or of the pus in the lesions.

Dr. H. A. Rykfogel of San Francisco discussed this paper.

**Affections of the Thyroid in California.**—Dr. Herbert C. Moffitt of San Francisco believed that affections of the thyroid, like aneurysms and early arteriosclerosis, were more common in San Francisco than many other cities of the United States. It was stated that 5 per cent. of the young women entering the University of California in 1904 had enlarged thyroids. Since January 1, 1905, he had noted moderate enlargements in 75, and large goiters in 8 patients, out of 546; 14 cases were in men. This gave a percentage of 15.2 in individuals nearly all of whom were native born, or who had lived in California for years. Of myxedema there were 53 cases from San Francisco, and 83 throughout the State. Thirteen had decidedly large thyroids, the myxedema resulting from changes in old goiters. Twice the condition resulted from operation on goiter. Emphasis in description was laid chiefly on skin, voice, and mental changes and disturbances in locomotion. Three women had frequent epileptiform attacks which did not yield to thyroid medication, although the skin and mental conditions improved. Endeavor had been made to distinguish between myxedema of thyroid and of mixed thyroid and parathyroid origin. Some attributed considerable influence to the parathyroids in determining sexual and mental changes. He had records of 61 cretins now living in the State and all native born. In a majority of them there was absence of palpable thyroid enlargement. Exophthalmic goiter appeared to be much more common in the country about San Francisco Bay than in other parts of the State. His list included 33 well-marked cases of exophthalmic goiter, excluding *formes frustes*. Of these 9 were in males, and 24 in females; 7 occurred in patients with goiters of years' standing. He said there was danger in labeling too many indefinite nervous affections with a convenient diagnosis of a *forme fruste* of exophthalmic goiter, which only a combination with cardinal symptoms would justify. He had seen enlargement of the thyroid with nervous symptoms and tachycardia, the result of masturbation in young men. The senseless administration of thyroid extract in large doses for obesity, arteriosclerosis, and other cases of supposed thyroid insufficiency, the speaker said, should be discountenanced. The reports of treatment in myxedema and cretinism were very enthusiastic. It was usually not necessary to give large doses of a good thyroid preparation; in cretinism he began with one grain daily, and rarely went beyond the 5 grains. Opinions were in accord that preparations representing the whole gland could not wholly be re-

placed by the active principle iodothyrin. It was very difficult to judge of the efficacy of any method of treatment in an affection notoriously so uncertain in course and symptoms as Graves' disease. From the evidence at command, it was not possible to say that the parathyroids were in any way influenced in Basedow's disease. The possible influence of the thyroid in California as an etiological factor in their very common arteriosclerotic and renal affections should be remembered.

Drs. James J. Walsh of New York, E. F. Wells of Chicago, C. Quevil of Tacoma, G. W. McCaskey of Ft. Wayne, Ind., George S. Whiteside of Portland, C. R. Grandy of Norfolk, Va., J. A. Lichty of Pittsburg, and C. Johnson of Clinton, Ia., discussed this paper.

**Value of Various Hemoglobin Instruments to the General Practitioner.**—Dr. M. H. Fussell and Dr. Marius B. Marcellus of Philadelphia called attention to the value of blood examinations in general. They used the Fleischel, Dare, and Tallqvist scale in the following manner: The blood of fifty cases was examined with each of the instruments. Each examination was made with at least two individuals, and frequently by three or four individuals. This was done so that the different instruments might be used upon the same case to discover any instrumental difference, and discern any *individual* difference, in the use of the different instruments. It was found that with the various instruments the differences were as follows: Average differences between Fleischel and Dare, 3.3 per cent.; between Fleischel and Tallqvist, 3.2 per cent.; between Dare and Tallqvist, 3.3 per cent. The personal differences: With Dare, 1.85 per cent.; Fleischel, 2.9 per cent.; Tallqvist, 1 per cent. The greatest personal difference was with the Dare, 15 per cent.; Tallqvist, 10 per cent.; Fleischel, 8 per cent. The conclusions were as follows: (1) Any one of the instruments studied by them was sufficiently accurate for practical purposes. (2) No practitioner should neglect to use one of these instruments, and the Tallqvist scale was cheap and reliable. (3) The Tallqvist scale could be used for routine observation, and either of the other instruments for detailed or more accurate work. (4) The Dare instrument was just as accurate as the Fleischel, and took much less time to manipulate.

**Election of Officers.**—*Chairman*, Dr. Herbert C. Moffitt of San Francisco; *Secretary*, Dr. J. S. Miller of Chicago; *Alternate to House of Delegates*, Dr. George Dock of Ann Arbor, Mich.

---

SECTION ON SURGERY.

*Second Day—Wednesday, July 12.*

**A Clinical Chart for the Record of Patients in a Small Hospital.**—Dr. George F. Wilson of Portland, Oregon, claimed that much scientific work is done in a great many hospitals throughout our country which is lost on account of a lack of clerical help, and the exacting duties of the resident staff in other directions. He presented a chart for criticism and suggestions which, preserved in its original form, included all necessary data, avoided the copying of histories, and when filed away or bound with a proper index, both of the patient and the disease, preserved all in a manner readily acceptable and did away with much clerical work in the way of repetitions.

Dr. Wright of Salt Lake City considered the chart was too large and that the spacing was not satisfactory.

Dr. Harry M. Sherman of San Francisco objected to the necessity of writing on both sides and to the fact that the chart was to be kept by some one other than the physician himself.

**Preliminary Report of a Study of Tetanus.**—Dr. James M. Anders of Philadelphia stated that the prevailing views showing tetanus to be a purely surgical isease were corroborated by his observation. He dealt with its distribution and prevalence in the United States; gave reports of endemic and epidemic occurrences with interesting cases of vaccination tetanus and puerperal tetanus, and tabulated cases not previously reported. He then followed with a brief review of the bacteriology, etiology, pathology, clinical history, and treatment, with special reference to the cases collected by himself; gave the results of the serum treatment and the conclusions drawn from his collective investigations.

Dr. L. L. McArthur of Chicago called attention to the importance of the early diagnosis of these cases and stated that in Chicago since the World's Fair, twelve years ago, it had been the custom among physicians to administer antitoxin in all cases of suspected or developing tetanus, before even receiving the report of the bacteriologist.

Dr. McCuster of Fort Wayne objected to the method of serum injection before a positive diagnosis had been made, and felt that the thorough cleansing of the wound was all that was necessary.

Dr. Walsh of Erie, Pa., reported a case of death from tetanus, although the patient had been thoroughly treated by him within an hour of the accident.

Dr. McLean of California dwelt at some length on the value of the antitoxin treatment and detailed the methods of its use.

Dr. Anders closed the discussion by arguing in favor of prophylactic treatment.

**Cysts of the Spleen.**—Dr. W. A. Bryan of Nashville, Tenn., gave a classification of splenic cysts with their etiology, structure, symptoms, and differential diagnosis. He also reported a case, reviewed the cases operated upon, and gave the results.

**Indications for the Removal of the Pathological Spleen.**—Dr. B. D. Davis of Omaha reviewed the recent physiology of the spleen; the several pathological conditions suitable for splenectomy; splenic anemia; malarial spleen; sarcoma; tuberculosis, and abscess. He reported a case of successful splenectomy and gave the clinical, blood, and pathological findings.

Dr. M. L. Harris of Chicago called particular attention to the blood condition in tetanus.

Dr. Charles A. Powers of Denver described some cases of cysts of the spleen on which he had operated.

Dr. Schleeter of St. Louis reported a case of rupture of the spleen in a boy fourteen years of age, and gave the blood count.

Dr. A. H. Cordier of Kansas City reported several cases on which he had operated, and urged a careful diagnosis before operation.

Dr. H. G. Marxmiller of Cincinnati considered that the subject should be divided into the medical and the surgical spleens, and advised the examination of a dried specimen of blood before operating.

Dr. McDonald of San Antonio reported a case operated upon by himself six years ago in a woman who has since borne children.

Dr. Jepson of Iowa thought the cases should be divided into two classes, the one to be called primary and the other secondary, and laid considerable stress on the blood count.

Dr. Griffiths of Kansas City reported the case of a child operated upon by himself, where the splenic condition followed a severe attack of whooping-cough.

Dr. Bryan closed with some references to non-parasitic cases.

Dr. Davis closed by calling attention to the blood variations before and after operation.

**Lip Operation for Cancer and Deformity, with Report of Cases.**—Dr. W. W. Grant of Denver described in detail a new operation for carcinoma of the lips and deformity of the mouth, which he claimed was superior to the ordinary operations for these conditions.

**Esophagectomy, with Report of Case with Prothetic Appliances.**—Dr. Wallace I. Terry of San Francisco showed a patient on whom he had performed his operation, which consisted of removing the upper portion of the esophagus down to the level of the sternum for recurrent

carcinoma; he having previously done a total laryngectomy.

Dr. Sala of Rock Island reported a case of cut throat where all the important blood vessels fortunately were missed and the man was eventually able to swallow fairly comfortably after the esophagus had granulated over.

Dr. Jacob Frank of Chicago mentioned a case similar to Dr. Terry's in which he had operated for carcinoma of the larynx, and in whom the remarkable result was obtained of the patient being able to articulate loud enough to be heard by everybody in a room with a seating capacity of three hundred.

**Cancer.**—Dr. William L. Rodman of Philadelphia called attention to the increasing frequency of cancer and the fact that not only was the parasitic theory not proven but that the weight of evidence was against it. He went into some detail concerning the diagnosis, prognosis, and treatment, both of the cancerous and of the precancerous stage.

Dr. A. W. Sherrill of Louisville reported having operated on three cases of cancer of the intestine, and expressed surprise at the frequency of this condition.

Dr. Tinos of Milwaukee urged that the operation when done should be radical and complete.

Dr. J. J. Hamilton of Idaho reported a case of cancer of the rectum for suggestions.

Dr. J. Clark Stewart of Minneapolis described an operation performed by himself for epithelioma of the lip.

Dr. McLenahan of Baltimore believed that cancer could be as well recognized by the naked eye as by a frozen section.

Dr. Martin of New Orleans called attention to the frequency of cancer among the negroes, although the general belief was that they were more or less immune.

Dr. Levings of Milwaukee called attention to the apparent relation existing between tuberculosis and cancer, and gave instances of families where this seemed to have been proven.

Dr. Rixford of San Francisco argued in favor of the removal of the glands in cancer of the breast.

Dr. Boucher of Hartford reported half a dozen cases of intestinal operations, most of them for cancer.

Dr. Parham of New Orleans described his method of operating in these cases, and referred to a method recently published in some German literature. He also stated that only negative results were obtained by the use of the Doyen serum.

Dr. Charles A. Powers of Denver believed that cancer was very likely to develop at the site of leucoplakia.

**A New Method of Incising and Suturing the Liver to Reestablish Its Continuity, and for the Control of Hemorrhage.**—Dr. Jacob Frank of Chicago described in detail his method of operating, particularly in the controlling of the hemorrhage. He stated that his chief object was to bring his flaps together, and obliterate all dead space, as this reestablished the continuity of the liver surface and left no raw surface or ragged edge.

**Gallstones in the Common Duct.**—Dr. W. D. Haggard of Nashville, Tenn., mentioned a number of cases on which he had operated, and looked upon stones in the feces as an indication for operation. He considered that operation in the presence of prolonged jaundice was dangerous, and mentioned a number of differential points between tumor and stone obstruction.

**Non-Calculous Cholecystitis.**—Dr. Davis S. Fairchild of Des Moines, Iowa, called attention to the number of cases operated upon for gallstones where no stones were found. In addition he mentioned that practically no changes were sometimes observed in the appearance of the gall bladder in spite of the supposed gall bladder disease.

Dr. McLaren of Minneapolis did not think that hemorrhage need be feared in operations on the liver. He, however, believed that stones in the feces were almost always associated with stones in the common duct.

Dr. Porter of Fort Wayne reported a case that had been perfectly well for ten years following an attack of gallstone colic, which finally came to operation for the relief of obstruction to the flow of bile.

Dr. Grothan of Nebraska did not agree with the statement that stones necessarily were still present in the liver because some had at some time been passed.

Dr. Cooper of San Francisco discussed the question from a medical point of view and called attention to important medical signs of gall bladder disease.

Dr. A. J. Ochsner of Chicago called attention to the three most important points in Dr. Frank's paper: (1) The importance of making distinct flaps, (2) the clean surface, and (3) the care required in closing the liver wound. He reminded the members that acute obstruction of the common duct was no longer operated upon in as great haste as previously, and that of late greater success had attended the operation. He briefly described an operation performed by himself, and claimed that the vomiting of bile was due to an anatomical fact.

Dr. J. H. Carstens of Detroit argued strongly in favor of more prompt operating and less medicating in cases usually diagnosed as gastritis, which were really nothing more than cases of gall bladder disease.

Dr. William J. Mayo of Rochester, Minn., spoke in favor of Dr. Frank's method of controlling hemorrhage in liver surgery, and added that the injection of hot water into the liver was very beneficial for the same purpose. He urged the necessity of carefully differentiating one's gall bladder cases, and reminded the members that one could never be sure a case was going to do well. He then dwelt upon the relation between jaundice and pain, and particularly the great variability of the former.

Dr. J. J. Hamilton of Idaho reported a case of gall bladder disease where the patient operated upon himself without an anesthetic, removed six stones, and made a good recovery.

Dr. Frank, in closing, believed it was possible to readily control hemorrhage in liver operations, and urged that liver surgery should be put on a plane with appendicitis.

Dr. Haggard closed by stating that he was always dubious about accepting the statement of a patient that they had passed gallstones unless they could produce them.

Dr. Fairchilds laid stress upon the fact that many of the most serious cases of gall-bladder disease occurred where no stones were present.

**Penetrating Wounds of the Abdomen.**—Dr. R. Winslow of Baltimore dealt particularly with military wounds, and stated that stab wounds are not as serious as gunshot wounds. He gave some of his personal experiences in civil practice, with the results of treatment.

Dr. Cooper of San Francisco referred to his experience with wounds of the abdomen as observed in the South African war, and called attention to the importance of the stomach being empty at the time of injury.

Dr. McRae of Atlanta detailed his method of treating gunshot wounds of the abdomen, and called especial attention to the danger in cases where the bowel was separated from the mesentery. He spoke in favor of the avoidance of the old method of using gallons of water in flushing the abdominal cavity after injury.

Dr. Willard of Philadelphia believed that posterior drainage was a valuable addition in the treatment of these cases where there had been much soiling of the intestines.

Dr. Boucher of Hartford considered that drainage was a decided disadvantage.

Dr. Winslow, in closing, believed that some cases should be drained, although where there had been but little contamination he did not think so.

**Meckel's Diverticulum as a Cause of Abdominal Crises.**—Dr. Miles F. Porter of Fort Wayne, Ind., reported having seen four cases inside of a few months, which induced him to write his paper, which included reports of 183 cases, of which 35 were not hitherto reported. He took up the causes of the condition together with the diagnosis and treatment, and expressed his belief that delay in operating was the chief cause of the great mortality.

Dr. Winslow of Baltimore mentioned two cases, one of which resulted fatally.

Dr. Jepson of Iowa expressed surprise that the condition was not found more frequently, and although he has been examining for the past two years every operative case, he has not discovered any.

**Phlebitis Following Abdominal Operations.**—Dr. A. H. Cordier of Kansas City considered this subject under eleven different headings, which included various operations in which the condition occurred, and the treatment, which he said consisted largely of an elevation of the affected leg, tonics, etc.

Dr. Tinos of Milwaukee referred to the advantage of the Trendelenburg position in the treatment of these cases.

Dr. Goldspohn of Chicago spoke of the author's reference to the predominance of the condition on the left side, and he believed it could probably be explained by the difference in the circulation of the two sides, the same as do the gynecologists.

Dr. Cordier, in closing, did not agree with Dr. Goldspohn, because he did not believe that the condition was of a thrombotic character.

**Anaerobic Cellulitis, with Report of Successful Cases.**—Dr. J. Clark Stewart of Minneapolis believed that this condition was becoming one of great interest to surgeons, first, because careful diagnosis is increasing the number of observed cases, and, second, because early diagnosis and prompt treatment has shown that life-saving results can be obtained by the proper methods.

*Third Day—Thursday, July 13.*

**Exstrophy of the Bladder Successfully Treated by Peter's Method, with Illustrations.**—Dr. Harry M. Sherman of San Francisco discussed, at considerable length, Peter's method, extraperitoneal, as contrasted with Maydl's method, intraperitoneal, particularly as regarded passivity of technique and results. He referred to the need of a ureteral catheter during the operation and the danger of it afterward. He considered the time of closure of the abdominal opening, and claimed that primary closure was preferable, although secondary closure was satisfactory. He concluded his paper by detailing at considerable length the case upon which he had operated by this method.

Dr. E. A. Wells of Hartford referred to two cases operated upon by Dr. Hartley of New York, one for exstrophy and the other for chronic tuberculous cystitis. He gave the details of the operations, both of which were successful, and advised great care in the use of the ureteral catheter and the doing of the operation when possible without opening the peritoneal cavity.

Dr. L. L. McArthur of Chicago referred to some experiments made by Dr. Peterson of Ann Arbor and Dr. Martin of Chicago with a method of implanting the ureter into the rectal wall so as to militate against the backward regurgitation. He claimed that the great advantage of their method was that the fecal masses did not tend to crowd into the ureter, thus materially lessening the danger of an ascending pyelitis.

Dr. Sherman closed the discussion by stating that he considered Dr. Hartley's method nothing more than the regular Maydl operation. He referred to some experiments made by Dr. Tait and himself on the transplantation of both ureters in dogs, all of which died from peritonitis. The only case where ascending infection had occurred following operation done by Peter's method was in one where Peter kept the catheter in too long. Dr. Sherman considered that the operation was exceedingly simple and very valuable.

**Tuberculosis of the Kidney.**—Dr. J. Garland Sherrill of Louisville believed this affection was worthy of more consideration than had generally been accorded it. He referred to the classification of Kroenlein of "solitary" and "combined" tuberculosis of the kidney, and to the modes of infection, and stated that the majority of cases showed the infection to be a descending one. The interference with the urinary outflow he claimed predisposed to both ascending and descending infection, and conditions that favored the development of the disease anywhere were particularly active here. After taking up the pathology, symptomatology, and diagnosis, and stating that if a diagnosis could be established early while only one kidney was affected much could be done for these patients, he referred to the following as the most valuable diagnostic symptoms: painful, frequent urination, polyuria, hematuria, pyuria with acid urine, and the presence on of bacilli. The methods of determining which kidney was affected, and the efficiency of the other, were given, and it was urged that these points should be determined before operation, except when other conditions demanded interference. In his opinion the operation of choice was complete nephrectomy or nephroureterectomy if the ureter was diseased.

Dr. O. C. Smith of Hartford advised persistent search for the tubercle bacillus in these cases. He urged the collection of a 24-hour specimen which should be searched several times, and if the germ were not found he advised that the specimens be centrifugalized and inoculation made into a guinea pig. Cryoscopy and skiagraphy were commended as valuable aids in diagnosis, and reference was made to an improved technique employed by Dr. Cole of New York.

Dr. M. H. Richardson of Boston stated that one of the first questions to be decided in these cases was whether or not both kidneys were affected, but still more important in his opinion was whether, in case of a proposed operation on one kidney, there was a second kidney, and if so if it was capable of carrying on the elimination. In his opinion the only way to treat this condition, provided the other kidney was sound, was by total extirpation. After removal of a tuberculous kidney, if sinuses existed that were dependent upon the tuberculous focus, he felt that the chances of a permanent cure were not worth much. In conclusion, he compared this disease with malignant trouble, and urged the same radical measures in its treatment.

Dr. Huntington of San Francisco agreed with Dr. Richardson in recommending the total removal of the kidney in these cases, and referred to three cases where this had been done with very good results. He recommended more optimism in the future in reference to the results of extirpation in the early stages.

Dr. Casper W. Sharples of Seattle referred to the importance of hemorrhage in this condition which he said might be associated with some irritation of the bladder and some painful urination, although not necessarily so. He related a case upon which he operated for tuberculous kidney which ended fatally from pulmonary hemorrhage eighteen hours after operation, although no evidence could be found of any tuberculous deposit in the chest.

Dr. Munzen of Wisconsin reported having observed Dr. Mayo inject 20 drops of carbolic acid recently into the ureter in a case of tuberculosis of the kidney to obviate the necessity of removing the ureter.

Dr. Jacob Frank of Chicago commented on the value of cystoscopic examination of the bladder in cases of tuberculous kidney, and stated that in his experience it was in the descending type and not the ascending that the ureter was generally enlarged. He spoke in favor of performing the operation of extirpation in two parts, and reported having opened the pleura accidentally while operating in one case, with the resulting death of the patient, although it was possible, in his opinion, that death was due to the failure of the kidneys to perform their function, and to the presence of stone. He also reported the case of a patient upon whom he operated sixteen years ago who had remained fairly well, although the bladder symptoms had never subsided. He urged the making of a diagnosis before the bladder had become accustomed to emptying itself so often, thus securing a better likelihood of bladder symptoms subsiding after operation on the kidney.

Dr. Sherrill closed the discussion by referring to the

question of passing the catheter through an infected bladder into a sound ureter, which he believed could be done with safety. He approved of Dr. Mayo's method of injecting carbolic acid into the ureter, provided the ureter was not very much affected. He looked upon the bladder symptoms as important and considered dysuria and polyuria as very early signs. When these were present he advised prompt search for the tubercle bacillus or for bacteria, preferably employing many specimens to looking at one specimen several times.

**Treatment of Congenital Dislocation of the Hip, With Report of Cases.**—Dr. Park Weed Willis of Seattle described in full his method of manipulative reduction by gentle repeated manipulation, stating that he resorted to open incision when, after a fair trial, manipulation had failed. He stated that he changed the casts with comparative frequency. The result in one case of double dislocation was anatomically perfect, and in another failure to maintain reduction. Upon making an open incision the capsule was found adherent across a very shallow acetabulum; reduction was performed, but the limb being found later on the dorsum reduction again became necessary; this was followed by an anatomically perfect result, although with stiffness and slight abduction. He also reported a case of double dislocation with poorly developed acetabular cavities. His result in this case was anatomically perfect, while in another similar one he secured anterior transposition. He concluded his paper with a report of two adult patients with single and double dislocation respectively, in whom he secured a good result with comparatively slight disability.

Dr. Hunkin of San Francisco urged the replacing of the hip in every case in the quickest and easiest manner possible. He stated there was no question about the best surgical proceeding being an open incision down to the capsule, division of the capsule, and putting the head of the bone in the acetabulum, provided there was one. He considered the great difficulty was to keep it there. In his opinion the most essential part of the operation was the wearing of a splint from six to ten months, and he advised that one which opened at the side be worn every night, even though it were dispensed with during the day.

Dr. De Forest Willard of Philadelphia referred to the hysterical nature of the newspaper articles on this subject a couple of years ago at the time of the visit of Dr. Lorenz, and spoke against his plan of treating these cases. He expressed himself as being in favor of Dr. Willis' procedure of gentle manipulation, provided it could be performed successfully, which he seemed inclined to doubt. He did not believe that a little improvement in the walking of children, and particularly of men, was important compared with their being better prepared to do their work. He reported the results of three operations performed on three of his patients last year by Dr. Hoffa, in none of which was a very satisfactory result obtained. Commenting on the prognosis he advised great caution, and compared the acetabulum in many cases to a tea-saucer instead of, as it should be, a tea-cup.

Dr. C. O. Theinhaus of Milwaukee reported having noticed that one more often had to deal with a hyperplasia in the acetabulum than a hypoplasia.

Dr. Harry M. Sherman of San Francisco believed that Dr. Willis had accomplished a great step in advance in the treatment of these conditions if he was able to secure and maintain the reduction by the methods he advocated. On general principles, however, he objected to the fearful manipulation of Lorenz or the bloody operation of Hoffa, and spoke in favor of the open incision.

Dr. Parker of Portland reported the case of a grandmother aged 60, and weighing 200 pounds, who had had congenital dislocation without any other discomfort than a limp; her oldest daughter had a similar condition on the same side, but her granddaughter was perfectly sound.

Dr. James E. Moore of Minneapolis protested against the use of the words "bloodless operation," saying it was a misnomer, and referred to it as the most unsurgical procedure with which he was acquainted. He believed the Lorenz method left the patients in a worse condition than they were before, and recommended open incision in the future.

Dr. S. C. Baldwin of Salt Lake City looked upon the Lorenz method as a very bloody one, and objected to the Hoffa operation. He believed that in the future the standard method of treatment would be the open incision along the lines described by Dr. Sherman.

Dr. A. J. Ochsner of Chicago reported having seen thirty cases operated upon with good results by the manipulative method, and believed it was a perfectly safe and justifiable procedure, provided the cases were properly selected and the operator thoroughly understood its performance.

Dr. Willis in closing, did not consider the open incision a justifiable surgical procedure, but claimed that it produced stiff joints and crippled patients. He believed enough germs could get into a small opening over one hip to ruin both hips, and called attention to the difficulty of maintaining the reduction after it had been successfully performed.

**Ununited Fractures in Cases of Delayed Union.**—Dr. Casper W. Sharples of Seattle, Wash., dwelt at some length on the symptoms, pathology, diagnosis, prognosis, and treatment of this condition. He also gave the details of a number of cases occurring in his practice with the results of treatment in each.

Dr. Martin of New Orleans believed that many cases of ununited fracture were due to improper reduction or the interposition of tissues, and advised making sure that crepitus could be elicited after reduction, this being, in his opinion, a sure sign of bony apposition. He was not in favor of cutting down in these cases unless absolutely necessary, nor did he believe that the use of wire was sufficient to hold the bones in place. He spoke in favor of the use of a staple made of piano wire, and advised drainage in all cases.

Dr. Huntingdon of San Francisco believed that in almost every case delayed union was due to faulty position. He felt that the use of the *x*-ray should make it possible to secure proper apposition, but he did not consider that the eliciting of bony crepitus was enough to decide that this result had been obtained. He looked upon fractures of the shaft of the femur as being particularly liable to become displaced owing to the strength of the opposing muscles.

Dr. Harry M. Sherman of San Francisco considered the tearing off of the nutrient artery the principal cause of delayed union, or non-union, in many cases. He called attention to the fact that the upper fragment healed alone and the lower fragment never did. He looked upon the existence of crepitus as a pretty satisfactory sign of the bones being in apposition, and recommended the use of the *x*-ray in addition, but spoke strongly against the *x*-ray being used for diagnostic purposes to the exclusion of the older methods.

Dr. Hunkin of San Francisco believed that the principal trouble was the failure to secure immobility at the seat of injury, and claimed that the profession was afraid to put the splint on tight enough for fear of swelling. He insisted that swelling would not take place, never mind how tight the splint, provided the pressure was evenly graduated, and recommended its tight application very strongly in all cases.

Dr. W. J. Means of Columbus looked upon delayed union as largely due to malnutrition. He did not believe ambulation did any good in the absence of apposition. He thought it wise to avoid the use of any material, absorbable or otherwise, unless compulsory, and claimed that he got better results when he did not drain than when he did drain.

Dr. Sharples, in closing, reported having gotten good results from the use of silver wire, but believed the saving of the periosteum was the most important factor in securing good union. He looked upon fibrous tissue intervening

between the ends of the bones as nothing more than an attempt to heal the parts. He agreed that the tearing off of the nutrient artery was most important, and felt sure he had seen cases of ununited fracture due entirely to that condition.

**Gallstones.**—Dr. L. L. McARTHUR of Chicago reported a very interesting case of gallstones, and showed the liver with the stones *in situ*. The important point was that for several days after he had removed all the stones he found they continued to pour out of the wound through a tube which he had inserted for that purpose.

Dr. C. O. THIENHAUS of Cincinnati considered the question of cholecystectomy and cholecystotomy, and felt that the experience of Dr. McArthur should have a direct bearing upon one's method of operating.

Dr. M. H. RICHARDSON of Boston did not feel that a surgeon should reproach himself, never mind how many stones might come away subsequent to his operation. He referred to some cases illustrating the formation of stones in the liver instead of in the gall-bladder, and mentioned a few symptoms by which one might at least suspect the existence of stones, even after an operation for their removal. In order to avoid the occurrence of this condition, he strongly recommended the employment of an incision large enough to admit the surgeon's hand.

Dr. ROBERT F. WEIR of New York suggested a method of securing a sufficiently large incision to enable one to explore the liver thoroughly.

Dr. McArthur, in closing, stated it was very evident that never mind how far into the liver substance one might go at the time of operation he could not be sure that all the stones had been gotten away.

**Fractures of the Leg, Their Diagnosis and Treatment, with Report of Cases and Demonstration of X-Ray Pictures.**—Dr. C. O. THIENHAUS of Milwaukee presented a large number of pictures illustrating several varieties of fractures of the leg, but more particularly of the foot, together with his method of treatment and the results obtained.

Dr. R. W. KNOX of Houston reported the case of a fireman whose foot was crushed by the driving wheel of his engine. Dr. Lorenz saw the case, and felt that reduction of the bones would be impossible, but upon the man consenting to operation it was performed with good results.

Dr. Thienhaus stated that if a subastragaloid dislocation could not be reduced immediately the open operation must be done, and if that was not successful the entire astragaloid must be removed.

**Officers.**—The Section elected Dr. Robert F. Weir of New York *Chairman*, and Dr. A. C. MacLaren of St. Paul, *Secretary*. Dr. A. F Jonas of Omaha was elected as the *Delegate to the House of Delegates*. The thanks of the Section to the Rector of the First Presbyterian Church for its use for the meeting, and to the retiring Chairman and Secretary for the excellent program, were carried.

*(To be continued.)*

---

**Gratitude Expressed in Babu.**—Dr. Margaret H. Norris, the physician in charge of the Sarah Seward Hospital at Allahabad, in India, furnishes beautiful evidence of the gratitude of the natives among whom she and many other American women are working in a medical way. The two letters subjoined are genuine, and from the husbands of women who had been patients of Dr. Norris:

"DEAR SHE:—My wife has returned from your hospital cured. Provided males are allowed at your bungalow, I would like to do you the honor of presenting myself there this afternoon, but I will not try to repay you; vengeance belongeth unto God. Y'rs, noticeably,

"_____"

"DEAR AND FAIR MADAME:—I have much pleasure to inform you that my dearly unfortunate wife will be no longer under your kind treatment, she having left this world for the other on the night of the 27th ultimo. For your help in this matter I shall ever remain grateful. Y'rs reverently,

"_____"

These testimonials are printed in the India number of *Woman's Work* for April.

**Contagious Diseases—Weekly Statement.**— Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending July 22, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 347 | 14 |
| Diphtheria and Croup | 181 | 26 |
| Scarlet Fever | 62 | 3 |
| Smallpox | ..... | ..... |
| Chickenpox | 43 | ..... |
| Tuberculosis | 365 | 150 |
| Typhoid Fever | 128 | 26 |
| Cerebrospinal Meningitis | 39 | 20 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1 165 | 239 |

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending July 22, 1905:

SMALLPOX—UNITED STATES.

| | | | CASES. | DEATHS. |
|---|---|---|---|---|
| California, Los Angeles | July | 1–8 | 1 | .. |
| District of Columbia, Washington | July | 8–15 | 6 | .. |

### SYPHILITIC SPINAL PARALYSIS. WITH SPECIAL REFERENCE TO THE TYPE DESCRIBED BY ERB.

BY WM. J. DOUGHERTY, M.D.,

NEW YORK.

ATTENDING NEUROLOGIST TO THE HOSPITAL FOR INCURABLES AND ST. JOSEPH'S HOME FOR THE AGED.

IN 1892 Erb described a clinical syndrome which he considered of sufficient importance to warrant its introduction into nosology as a definite form of spinal cord disease. To this syndrome, the distinguishing features of which are feebleness in the lower extremities, more or less spasticity and exaggeration of deep reflexes, together with vesical and possibly rectal derangement, and slight but quite constant disturbances of sensation, he gave the name of syphilitic spinal paralysis. He assumed the disease to be syphilitic, although pathological and anatomical proof was not obtainable at the time, from its occurrence almost exclusively in individuals who had suffered a luetic infection. In the absence of post-mortem evidence, Erb localized the lesion in both halves of the cord in the dorsal region, chiefly in the posterolateral tracts, together with partial involvement of the posterior columns, both gray and white. He did not commit himself as to its probable histological nature, and this is even now a question over which there is much divergence of opinion.

FIG. 1. Sixth Cervical.

It was some time before evidence accumulated tending to show the nature and distribution of the lesions underlying the process which Erb designated as syphilitic spinal paralysis. Later observations with autopsy findings were not uniform, indeed conflicting. Westphal, Eberle, Nonne, and Williamson reported cases some of which were diagnosticated as spastic spinal paralysis, but all unquestionably typical examples of syphilitic spinal paralysis. The lesion in these cases (four in all) consisted of a combined system disease most often involving the pyramidal, cerebellar, and Goll's tracts, with, in one case, implication of Burdach's tract as well. On the other hand, not a few cases have been reported embodying all the clinical phenomena of syphilitic spinal paralysis where the pathological basis was apparently a myelitis most often encountered in the mid-dorsal region. These cases, which were reported by Nonne, Dreschfield, Williamson, Long, and Wike, revealed, in addition, an ascending and descending degeneration, but how much of this

FIG. 2. Eighth Cervical.

was primary (if any) or secondary is difficult to determine. It would be well here to direct attention to the fact that previous to the appearance of Erb's monograph on syphilitic spinal paralysis, an identical symptom group had been recognized by Charcot and Marie and designated "syphilitic transverse myelitis."

Erb, in an address delivered before the Post-Graduate Hospital, West London, in 1902, in describing those cases of syphilitic spinal paralysis in which the lesion was a myelitis with ascending and descending degenerations, in part said: "I will only point out that a multiple (combined) system degeneration in the lateral and posterior tracts is common to all. The secondary or primary nature of which, however, is difficult to determine or define because there is an addition in the dorsal cord, a patchy, more or less complete transverse lesion. But I must say that I am strongly of the opinion that the main factor

FIG. 3. First Dorsal.]

is the combined system disease, by the side of which the transverse lesion appears as etiologically a quite permissible complication."

As one becomes familiar with the literature of syphilitic spinal paralysis he must be impressed with

the fact that this syndrome is not the expression of any definite pathological process. That it is in the greater majority of cases dependent upon syphilis we will admit, and admitting this we should be prepared to encounter any of the multitudinous degenerative tissue changes which this insidious and destructive infection is capable of engendering. Much light, I believe, may be thrown on this phase of the subject if we take into consideration the length of time that has elapsed between the primary infection and the onset of symptoms indicating involvement of the spinal cord. Those cases developing within a few years after the luetic infection, even though they be slow in onset, may be looked upon as an expression of secondary or tertiary syphilis, which, as we know, is chiefly characterized by an active cellular infiltration, the immediate cause of which need not be discussed here. On the other hand, if a considerable period of time has elapsed between the syphilitic infection and the beginning of symptoms referable to the spinal cord, it may be assumed with a great degree of certainty that we are dealing with changes produced by a more advanced stage in the evolution of syphilitic infection, and in a previous article I have suggested that this stage be called *terminal syphilitic*. It is in this stage that we encounter the system degenerations of the cord, for instance, tabes, occasionally combined sclerosis, and possibly also certain primary degenerations of the motor tracts, and it would seem to be cases of syphilitic spinal paralysis occurring at this period which led Erb to believe that the basis of this paralysis was a system degeneration of

Fig. 4. Third Dorsal.

the cord. Certainly the cases reported by Eberle and Nonne and cited by Erb in support of the systemic basis of this disease, must be placed in this category. In Eberle's case the disease began at the age of 46, the patient having contracted syphilis 18 years previously; he died after 10 years. The changes in the cond consisted of a combined system disease of the pyramidal, direct cerebellar, Goll's and Burdach's tracts. No other changes were observed. Nonne's patient was a man 51 years old, who had contracted syphilis at the age of 32. He died of cancer five years after the onset of the paralysis. There was found a typical combined system disease of the pyramidal and direct cerebellar tracts with also slight degeneration in Goll's columns. We have, therefore, in these two cases the analogue etiologically and histologically of that most typical manifestation of terminal syphilis—tabes.

Turning to syphilitic spinal paralysis as an expression of an earlier period in the evolution of the syphilitic poison, I am very fortunate in being able to present detailed histories and pathological findings of two cases obtained on the service of Professor Pierre Marie, to whom I take pleasure in acknowledging my indebtedness. It would seem indicated, however, before placing these cases in the category of syphilitic spinal paralysis, as described by Erb, clearly to define just what this author considers its essential features, and that no doubt may exist in the mind of the reader, I incorporate Erb's own remarks on this subject: "It would be

Fig. 5. Sixth Dorsal.

essentially pedantic to lay down hard-and-fast rules here, but still I think that the picture as I drew it at first still holds good completely. Should such a patient enter your consulting room, gentlemen, you would notice his labored gait, with tightly closed, stiff legs, his feet sticking to the ground, scraping at each step, often walking with the aid of a stick—a picture of extreme spastic gait. On examination you would find weakness, more or less well-marked paresis of the feet and legs, the muscular rigidity being often slight compared with the change in the gait, but sometimes sufficiently strongly marked. You would find, moreover, an enormous increase in the tendon reflexes, patellar clonus, ankle clonus, and usually the Babinski reflex; on the other hand, there would be usually only slightly marked subjective and objective disturbance of sensation, which might be discovered only on closer examination. There would be more or less weakness of the bladder, especially incontinence, but also retention of urine,

Fig. 6. Eleventh Dorsal.

so that the patient could not avoid the use of the catheter and the urinal, and usually there would be some weakness of the generative organs. In the arms there usually would be nothing except slight increase in the tendon reflexes. The head and the cerebral nerves, the pupils, the eye muscles, the speech, the intellect, etc., and also the vertebral column, would be unaffected. In a case presenting such a picture you might at once think of syphilitic spinal paralysis, and on questioning the patient you would also learn that he had some time ago, or recently, been the subject of specific infection, more or less severe, and that he had been treated more or less thoroughly; that his complaint began slowly and

insidiously, usually at first in the legs, with gradually increasing weakness and stiffness; that he got tired sooner; and that there was usually no pain whatever, but all kinds of paresthesia. In some cases, not infrequently, bladder trouble is the first, and for a long time the only symptom; in all cases bladder weakness occurs in greater or less degree during the course of the illness. Otherwise the patients have usually nothing of importance to tell. Sometimes they give as an additional cause some injury, cold or excess, or some physical shock. Occasionally they describe the illness as having come on more rapidly, almost acutely, followed by improvement and subsequent relapse."

Case I.—Male, aged 61 years, occupation, driver. Father died at 56 from hemiplegia. Aside from this the family history is negative. He was never seriously ill, nor was he addicted to the use of alcohol or tobacco. In 1886 he contracted hard chancre, followed by mucous patches and skin eruption. He was under antisyphilitic treatment for about two years, although during this period he did not take medication regularly. In 1892 he suffered from a sudden attack of aphasia, with considerable mental agitation, from which he began to recover after the fourth day, and in about three weeks' time was quite well. Some few months later he began to experience difficulty with walking, and some loss of dexterity in hands. This impairment of dexterity disappeared, however, in a very short time. About fifteen months later (1893) his gait had become very spastic and he complained of considerable paresthesia in the legs, and again of loss of dexterity in hands. The following year (1894) he complained of incontinence of urine and feces. Before this, for some time, he had difficulty in starting the stream. The incontinence was intermittent and in the early part of the following year it ceased, but would return whenever the patient overindulged in eating or drinking, which, however, was not often. In the latter part of this same year the incontinence of urine reappeared, and since then has been an annoying factor. He has suffered at times from both dull and shooting pains in the legs, although the pain has not been very distressing. Examination made in 1894 revealed the following: Gait typically spastic; reflexes of lower extremities

Fig. 7. First Lumbar.

exaggerated; no ankle clonus; cremasteric reflex absent; abdominal reflex slight; no loss of dexterity in hands, but a very coarse tremor when they are extended; elbow and wristjerks exaggerated; no disturbance of deep muscular sensibility; general tactile sensibility normal; analgesia in lower right extremity; and on the remainder of the right side, including arms, the prick of a pin gives a burning sensation; absence of thermic sensibility in lower right extremity and diminished in left lower extremity. Pupils normal, as are the pharyngeal reflexes and innervation. To this history in 1901 the following notes were added: Babinski phenomenon present on both sides; gait extremely spastic; complete incontinence of urine, *i. e.* his urine passes without his knowing it, although it is not constantly passing; sensibility normal in all parts of body, legs excepted, where the sense of pain and touch is diminished. Contralateral reflex present; no ankle-clonus; cremaster and abdominal reflexes present, though weak; pupils normal. He complains occasionally of dull pain in leg and some paresthesia in hands. Patient died June 29, 1903, of nephritis. At the time of death there had not been noted any change in his nervous symptoms.

In this case, which represents the meningomyelitic, or as we would call it the marginal type of syphilitic spinal paralysis, we find in a considerable vertical extent of the cord a variable marginal sclerosis. In places the sclerosis embraces the entire circumference of the cord, but on the whole it is more marked in Gower's, Flechsig's and the crossed pyramidal tracts, and is associated with thickening of the piamater, due to the presence of newly formed connective tissue bundles. The distribution of the lesion is best illustrated in the accompanying drawings (Figs. 1-7). Its upper level

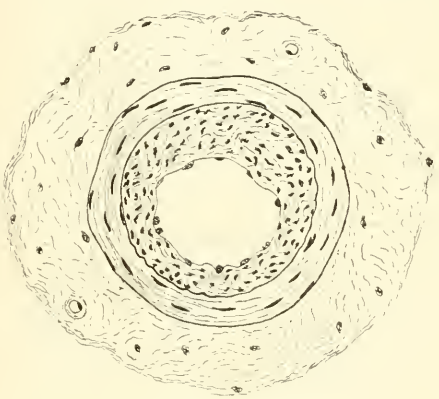

Fig. 8. One of the vessels of the posterior roots.

corresponds approximately to the sixth cervical segment; here we find the sclerotic zone completely investing the cord, though, as will be seen, it is relatively slight in the anterior and posterior regions, while in the lateral areas it is quite pronounced. This latter fact, we believe, is to be explained in great part by an ascending degeneration in the columns of Flechsig and Gowes, as at this level there is very slight vascular or meningeal involvement. Following the sclerosis down through the cord, we find its maximum development from about the eighth cervical to the second dorsal segment. Then it gradually becomes less intense, being limited to the lateral and anterolateral areas until below the twelfth dorsal segment it disappears entirely. Sections from the lumbar region show only a secondary descending degeneration of the crossed pyramidal tracts. In addition to the marginal sclerosis as we have described it, one observes a degeneration in the columns of Goll which commences quite abruptly at the third dorsal segment, sugesting at first glance the possibility of a transverse lesion. This, however, does not exist, but instead we find on examining the posterior roots scattered degenerated foci resulting from an obliterating endarteritis. Thus the degeneration in the columns of Goll is readily explained.

The involvement of the vessels of the posterior roots is quite extensive and corresponds in vertical extent to the thickened pia mater and marginal sclerosis. Fig. 8 shows one of the involved vessels of the posterior roots with its thickened intima and the voluminous adventitia.

Case II.—Male, aged 41 years, married, carpenter. His family history contains nothing of importance. He never suffered from any illness aside from measles at the age of five. At sixteen he had a soft chancre, followed by a suppurating bubo. In 1888 he was infected with syphilis, and six weeks later developed mucous patches in the throat and anus. No treatment at this time. In 1892 had gummata of hands and legs, and at this time received antisyphilitic medication for two months. During the early part of 1893 he complained of some pain about the waist. Three months later, after a "spree," he was seized with severe pain at the waist, accompanied by priapism. He at this time suffered from retention of urine. There was also marked hyperesthesia of the lower extremities. His condition became rapidly worse, weakness of the legs ensued, and at the end of one week he was conveyed to a hospital completely paraplegic. Concerning his condition at this time, all that he can say is that he did not suffer; his knees and Achilles jerks were exaggerated, and there was no clonus. Under proper medication he slowly improved, and in six months was able to leave his bed, and two months later, with the aid of crutches, he could walk about. After this he improved but little, and on December 29, 1888, was admitted to the Bicêtre. On examination the following facts were obtained: Patient well nourished; gait very spastic, keeps eyes on ground like a tabetic, feet drag along ground on toes, and at the end of each step he brings his heel forcibly to the ground; knee and Achilles jerks very exaggerated, and clonus easily obtained; no incoordination, and muscular strength of legs good, but a little less than normal. There is no muscular atrophy, and deep muscular sensation is normal. Romberg's sign exists. The arms, head, and special senses are normal, as is objective sensibility, with the exception of a small area on right side five cm. in width, extending from the median line in front just below the umbilicus, to the vertebral column, where sensation in all

Fig. 9. Showing the marginal type of lesion.

forms is diminished. At times slight pain in dorsolumbar region. The patient complains of urgency in urination, and occasionally nocturnal incontinence. His bowels at times are incontinent. Sexual desire and capacity gone. In 1901 the following notes were added to his history: Deep reflexes of lower extremities exaggerated. No ankle-clonus. Plantar reflex of the flexor type. Controlateral reflex very pronounced on both sides. Slight exaggeration of the wrist-jerks, most marked on the left side. Reflexes of jaw present, though weak. Cremasteric reflex absent. Abdominal reflex slow.

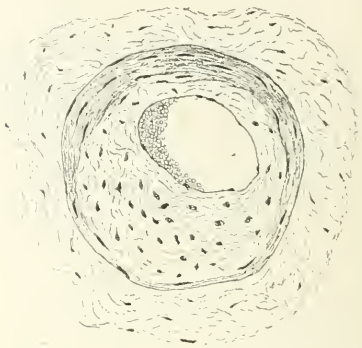

Fig. 10. A partially occluded branch of the spinal artery.

Pupils equal, respond to light, though not very actively. Romberg sign very marked, especially so for the past three years. Complains of urgent urination; sometimes he has difficulty in starting the stream, or again, there is complete retention. Occasionally his bowels move involuntarily, but as a rule they are constipated. Some sexual desire and capacity. Gait slow and very spastic. Strength of lower extremities fair and of upper normal. Patient presents all the advanced signs of arteriosclerosis. November 12, 1903, this note was added: Patient in last stage of pulmonary tuberculosis. Signs and symptoms referrable to spinal cord have not changed since last recorded observation. He died November 14.

In describing the changes found in the cord of this case, we will at the same time briefly compare them with those of Case I. This second case illustrates what we may regard as clinically a different type of syphilitic spinal paralysis, though in point of fact it is etiologocally and histologically the same as the first case, the difference being simply as regards the intensity of the process and its confinement to a limited area of the cord. It illustrates the type due to a transverse lesion—a localized transverse, subacute or chronic myelitis. Consequent upon this transverse lesion are the usual ascending and decending tracts of degeneration. Just above and below the transverse lesion we have, to a limited extent, the marginal type of lesion. This is best seen in Fig. 9, taken from below the lesion, and this section also reveals some scattered degenerated fibers in the posterior columns. The condition of the blood vessels and meninges is similar to that of the first case, the chief difference being that these structures are not so extensively affected, that is, the vascular lesions are not distributed over so large a territory, and this fact, in my opinion, explains the difference between the two types.

In the first case the vascular lesions have quite an extensive vertical distribution. There is endarteritis of the vessels of the posterior roots and pia mater, which in turn has induced a corresponding circumferential layer of sclerosis in the cord. The sclerotic zone in this particular case is dense and but slightly cellular because of the rather long duration of the process. In certain rare instances, when death ensues shortly after the inception of the process, the

lesion is quite different in structure. Dr. Van Giesen tells me that he has seen and examined one such case dying of an intercurrent disease, twelve months after the onset of such a marginal type of spinal syphilis of subacute course. In this case the zone was richly cellular and apparently still in an active stage of neuroglia proliferation.

In the second case, as in the first, the cardinal factor is the vascular involvement, but here the circumstances are somewhat different. The vascular changes are local and consequently the lesion is more or less confined. This is clearly shown at the eighth and ninth dorsal segments, where we find pronounced changes in the vessels. See Fig. 10, which presents a partially occluded branch of the anterior spinal artery.) These changes, instead of being scattered over a large vertical extent of the cord, are localized and concentrated over these segments, and are the direct cause of the more or less complete transverse lesion here encountered.

So it is the distribution and dissemination of the vascular lesions rather than any special difference in their nature which determines which of these types of spinal syphilis shall ensue. Of course, these deductions are made from a study of only two cases, and a third which Dr. Van Giesen has very kindly placed at my disposal. But still, in trying to approach the problem independently, they appear to be well defined, and must be illustrations of great numbers of similar cases which have occurred before and will occur again, and finally they seem clearly to demonstrate that the so-called Erb's syphilitic spinal paralysis is not, as Erb is inclined to believe, necessarily dependent upon a system disease of the spinal cord.

# COPPER AND ZINC POISONING—BRASS POISONING.

BY MONTGOMERY H. SICARD, M.D.

NEW YORK.

INSTRUCTOR OF PHYSICAL DIAGNOSIS IN THE CORNELL UNIVERSITY MEDICAL SCHOOL; MEMBER OF THE NEW YORK ACADEMY OF MEDICINE, ETC.

THE subject of this article is a condition which occurs widely distributed among workers in brass and bronze, whether they be melters, casters, dippers, polishers, or filers. In treating of the subject, however, it will be necessary to say a few words also upon the effects of copper and zinc, of which metals brass is chiefly composed. It has been my good fortune to see a number of workers in these metals at the Cornell University Medical College Dispensary, and to investigate the condition among many workmen in the various foundries in and about New York.

*Copper.*—Copper occurs mostly in the United States as pyrites, the sulphide of copper with iron; other forms of occurrence are—cuprite, the red oxide—melaconite, the black oxide—malachite, the green carbonate; it is also found native. Pyrites occur also with lead, arsenic, zinc, antimony, mercury, gold, or tin. Very frequently this sulphur ore is roasted first for the extraction of sulphur in the manufacture of sulphuric acid, and the resulting product, which still contains the unchanged minerals, is smelted for copper; this resulting slag somewhat resembles coal clinkers and gives rise to a great amount of dust when handled.

The filling of the furnaces is a most laborious occupation, and as the amount of dust is tremendous, men find it necessary to keep their mouths covered with cloths. The furnaces are high and are filled from the top, and the sulphur dioxide, which is sometimes almost overpowering, is intensely irritating to the respiratory tract, and causes a languor and depression that nearly incapacitates a man for work. It is difficult to get men to work long at the first smelter, and the employes are constantly changing, as they will not stand the severity of the work and the unwholesomeness of the atmosphere. In one of the largest smelting concerns in this country, I was unable to find a man who had worked in this department longer than eight years. Coughs are common among the men, and not infrequently pulmonary tuberculosis is the consequence.

After the ore is melted it is collected into a large tank from which it runs into moulds for cooling. Here, if lead and arsenic be present in any quantity, poisoning is common; lead oxide is extremely volatile, and hence readily inhaled; vomiting, colic, obstinate constipation, joint pains, blue line, and paralysis are to be found. In lead mines, and in lead smelters as well, there is a class of men known as cripples, who stand around and do a little light work, such as sweeping up, etc.; these men, of course, are suffering from lead or arsenical paralysis.

From the first smelter the copper is again melted, is subjected to the Bessemer blast furnace, remelted a number of times at from 2,500° F. to 3,000° F., until at last refined, when it consists of about 99.5 per cent. pure copper. Ill effects from working it are less and less distinct until it reaches refinement, when no ill results occur. Specifications for ingot copper issued by the United States Navy Department are as follows: "To be practically pure copper, free from all other materials, sulphur, and all other impurities, etc."

*Zinc.*—Zinc is obtained from a blend which contains a sulphite with many impurities, chief among which are lead and arsenic. The roasting of zinc blend is very detrimental, owing to the dense fumes of sulphurous acid which are given off, and to the deflagration of zinc oxide (which will later be spoken of more in detail). Lead impregnates the zinc vapor, and arsenic is almost always present. Specifications for slab zinc issued by the United States Navy Department are as follows: "To be practically pure metal, free from sulphur, arsenic, or antimony, and to contain only traces of iron, and not to contain over one-half of one per cent. of lead."

*Brass.*—Brass is an alloy consisting of copper and zinc, varying somewhat in proportion as to the quality of metal supplied. Yellow brass consists of copper, 50-60 per cent.; zinc, 35-40 per cent.; lead, ½-1 per cent. Bronze is a high grade brass, and consists approximately of the following: Copper, 86 per cent; tin, 2-4 per cent.; zinc, 8-10 per cent.; lead, 2 per cent. All these proportions are subject to variation; tin especially, being very expensive, and being very hard in composition. is usually economized in, and may run as low as a fraction of 1 per cent. Different factories have their own formulæ, according to the ultimate use of the metal they produce.

The foundry is a room which contains from twelve to twenty-four sunken furnaces, into which are placed the crucibles containing the copper ingots to be melted; scrap brass is often added, and when the whole is molten (in about one and one-half hours), zinc, commonly called spelter, is added. Upon this addition the zinc deflagrates unless the furnace be covered; after heating at 1,800° or 2,000° F. for two and one-half hours, the crucible is raised, the slag scooped off, and the metal is poured into sand-coated iron moulds. Immediately upon pouring, the deflagrating zinc fills the air as a heavy, dense cloud of white, finely divided particles. In good weather these rising fumes are carried off by the means of ventilation; but in damp, foggy, or rainy weather, when the atmosphere is heavy, the smoke does not rise, but fills the foundry, and exerts its most deleterious effect. Those who are not in the immediate neighborhood of the crucible escape to a great extent the irritation of the rising fumes, but the falling ash of zinc oxide fills the air, is inspired by all the workers and settles upon everything, including their persons. In poorly ventilated foundries there forms upon the rafters a white incrustation of zinc oxide. To one unaccustomed to the metallic vapors the feeling is one of choking, metallic taste, burning thirst, constriction of the thorax, suffocation, and giddiness; the open air is sought with much relief.

*Brass Founders Ague.*—Brass chills, spelter fever, or spelter shakes, are the names by which the inhalation effects are known to the workers in this metal; the attacks are so clearly defined as to simulate in the minds of the sufferers attacks of malarial fever, and, though of common occurrence, are not well known to the average practitioner of medicine.

The so-called chills are most apt to occur among the new workers who are unaccustomed to the smell and effects of the vapors. Upon leaving the shop and being in the open air (occasionally, however, in the foundry), the attack begins suddenly with a feeling of languor, headache, shivering, and with extreme pallor; the prostration becomes intense; the headache severe, and the shivering sometimes amounts to a distinct chill, with nausea and profuse sweating, and is sometimes followed by a feeling of heat; aching pains occur in the muscles, with weakness of the limbs; vomiting frequently ensues. Such an attack lasts six or eight hours, and the patient awakes the following morning with a feeling of lassitude in proportion to his immunity. The attacks seem to vary in different individuals, some being more suspectible than others. As said before, the new workers are the ones most affected, but even of these there are some who escape with but few and comparatively slight attacks. The old workers are, to a certain extent, immune from these acute seizures; their attacks are at infrequent intervals, less severe, and less typical than the one described. The men continue their work with comparative ease and comfort until the return of a cold, foggy, damp day, when some one is sure to suffer. Absence from the foundry for a fortnight or even for a shorter period, predisposes to an attack, and return will probably be met with another seizure. I have been told by old workmen who have been in the foundry for many years, that upon return to work on Monday morning they inhale the fumes with a feeling of pleasure and exhilaration; some of these men have occasional attacks, consisting, however, only of languor, perspiration, and headache. There are others among the old workers who have not had an attack for many years, have grown fat at the work, and who say that the metal working is conducive to good health.

The ague seizure is so well recognized that the help of a physician is seldom, if ever, required; it is transitory in its course and the patients have learned to treat it themselves. Free sweating is the thing most desired, and for this, hot milk, hot lemonade, and whiskey are the means usually taken; milk forms an insoluble albumenate and is thus the most efficacious; however, as milk is often looked upon with contempt, we find that whiskey is the drug mostly resorted to by this class of men who are addicted to its use. Milk and lemon juice have their advocates, and these say that alcohol dose them more harm than good. Whatever the means taken, the patient awakens, after a night's rest and free sweating, recovered from his chills, with a feeling of lassitude in proportion to his immunity, this languor being little or none in the case of old workers.

The men who continue working under these conditions show the changes due to other kinds of dust inhalation, and suffer to some extent from cough, constipation, and occasionally colic. One reads that this class of workers are lean, spare, sallow, men; it is true that many, if not all, show a distinct gray pallor, but almost all are large, powerful, muscular men, some even given to obesity, and there are many who have worked at the business for twenty-five or thirty years, with scarcely a day off. Thackrah found in Leeds only two brass founders over forty years of age; this, however, is a very low limit, for I personally have seen many above that age, and some between sixty and seventy years. One does not see many workers above fifty, however, but it can be partly ascribed to the severity and laboriousness of the occupation; to the same cause can be ascribed the size and strength of the men, for unless possessed of considerable muscular power, they find the work too arduous.

From my personal knowledge and contact with many copper and brass workers, and from conditions as I have seen them, I cannot think that brass working (as done here) is as unhealthful an occupation as the older writers, and especially the British investigators would lead one to believe. Beyond the respiratory effect such as would be caused by any dust, I cannot see that the inhalation of the metal does much harm; true, we see chronic bronchitis and emphysema among them, but these are prevalent conditions in all walks of life; fibroid lung so much described by the older writers is not so much seen at the present time, probably owing to the more perfect and scientific methods of diagnosing pulmonary tuberculosis, which I think most of the former cases of fibrosis have proven to be. The results I consider very largely a matter of ventilation, and where this is good, disastrous effects are not so apt to occur.

In old and small foundries, which are hard to heat in cold weather, windows and traps may be kept tight shut, the amount of falling zinc oxide is great, and men frequently have chills while at work. Most of the foundries from which I have collected my material have been fairly well ventilated rooms, but the conditions I have heard described by foreign born employes as existing in the old country, where the furnaces were in the cellar, the ceilings low, and ventilation poor, make a vast difference in the ultimate effect of the metallic poisoning.

As to the causative factor, I think without doubt the chills are due to the deflagrating zinc, and this is so considered by the men themselves. Doctor Hogben of Birmingham considers them, however, due to copper rather than to zinc, and bases his conclusions upon the following facts: "Zinc given in any quantity produces no such symptoms; in the process of galvanizing, these symptoms do not occur; unlike copper, lead, and mercury, zinc is not

cumulative." Arlidge says, "Similar symptoms occur among brass workers where no zinc vapor is thrown off."

One can get chills, however (and men frequently do get them), without working near enough to the crucible to inhale the rising fumes, but through being subjected to the heavy shower of zinc ash. Examination of this deposit has shown it to consist of zinc oxide, but to contain no arsenic. The chills never follow bronze making where the copper is as high as eighty-six per cent., and the zinc is only ten per cent., the fumes here being comparatively slight. Sometimes bronze is exclusively poured for two weeks, after which time brass is again made; upon resuming brass pouring, every one in the vicinity will come down with an ague seizure. Copper workers who deal with the refined molten metal (that is the finished product such as is used in brass making) do not have such attacks. In the roasting of zinc ore that contains no copper, the workmen complain of the same symptoms—intense languor, depression, rigors, vomiting, pains. Oxide of copper is non-volatile, while oxide of zinc is very volatile.

Thackrah in 1830 was the first to recognize the peculiar form of poisoning called brass founders' ague, and which he ascribed to the zinc constituent. He described the seizure incompletely and erroneously as an intermittent affection occurring once a month or once a year. The disease was further described in 1862 by Dr. Headlam Greenhow, who referred chiefly to the bronchial effects. He speaks only cursorily of the nervous symptoms, and thinks the trouble due to zinc. Simon says brass is recognized as an unhealthful occupation by both workers and employers, and that workers never attain old age. The Birmingham dispensary shows enormous numbers of brass workers complaining of pulmonary and gastric disorders; but among 30,000 patients he has never personally seen a single case of ague.

In sand casting a clay mould is made, into which the remelted brass ingots are poured; this mould is covered with a coating of plumbago, charcoal, flour, or powder of loam, and when the metal is poured into it the fumes of zinc again arise in addition to the dust of the coating. The men in this department have occasional ague seizures, but the dust is not sufficient to cause much permanent respiratory embarrassment.

At the dipping vat, the greatest and most serious results arise; this vat contains a strong solution of nitric or sulphuric acid, in which, metal which has become oxidized is dipped for cleaning. This is notoriously bad work, the men developing cough, increasing pallor, and emaciation; sometimes death ensues. Where much dipping is done, men cannot work for more than three to four years, the increasing emaciation incapacitating them for work. The men themselves realize the danger of this occupation and say that the victims die of erosion of the lungs, or of consumption. As a matter of fact, pulmonary tuberculosis is a natural sequence. It is difficult to devise any means to offset the inhalation effect of the acid baths; some foundries have hoods arranged to carry off the fumes, but unless forced suction is used they are useless, and in any event the fumes corrode the metal.

Sand blasting is an operation which has come into vogue during very recent years, and is a means of cleansing metal by a stream of sand under high air pressure. The workman wears over his mouth a mask containing a damp sponge, and over his head puts a windowed helmet which comes well down over the shoulders. Even with these precautions he inhales much dust, which causes considerable respiratory irritation and gives rise to cough.

Brass filers sometimes show the mark of their occupation. In elderly men with gray hair and moustache, we frequently see a decided green discoloration of the hair; this is due to stroking, or passing through the hair, hands that are covered with brass filings and dust. Likewise, in hot weather, when perspiring freely, the sweat looks green and discolors the underclothes; this, also, is due to the dust on the body surface and in the clothing. The teeth are usually in poor condition, and greenish discoloration of the tartar along the bases, especially of the incisors, is sometimes present. The men are apt to suffer more from gastrointestinal difficulties than from bronchial effects.

Polishing was formerly a deleterious trade, the metal being cleaned on an emery disc; a fine brass dust is caused, which, unless carried away by forced draught, encircles the worker, settles on him and is inspired by him. Formerly, polishers wore masks of wet cloth or sponge over the mouth for protection, but during recent years hoods have been arranged which catch the dust, and by suction convey it to tubes which carry it away. Where these hoods are not used, or are imperfect, dust fills the air, and chronic diseases of the upper respiratory passages and of the lungs always result. A disagreeable complication is eczema of the groins, scrotum, and perineum, which results chiefly in hot weather, when the perspiration of the parts and the metal dust together cause considerable irritation.

Gastroenteritis is not uncommon among filers and polishers; nausea, vomiting, metallic taste, epigastric pain, constipation, are due to the brass dust which is upon the surface, and which is transported from the hands to the mouth, and so reaches the stomach.

The green discoloration before spoken of is best seen among copper workers, especially those who handle blue vitriol; from the hands they transfer it to other parts of the body. Next to the vitriol handlers it is most apparent among men who turn the copper ingots into water to be cooled, and are enveloped in the rising steam. White horses working around copper smelters are sometimes turned green. The discoloration of the hair of workmen is sometimes so great as to be a source of annoyance.

According to Layette, chills occur among workers in metals other than brass, and he attributes them to overheating and exhaustion. He says, however, that in copper poisoning, green hair, green sweat, green teeth occur, and according to observations made at Durfort, France, the bones are discolored green. As a result of swallowing and breathing copper dust there is burning in the throat, loss of appetite, nausea, vomiting, constriction of the chest, colicky pains, soreness of the abdomen, and mucus discharge from the bowels; anemia, dyscrasia, conjunctivitis, bronchitis, emphysema, and fibroid phthisis.

In Guy and Ferrier's Forensic Medicine there is recorded an outbreak of copper poisoning from the use of copper vessels in cooking, in which the symptoms were almost identical with those mentioned.

Simon agrees that brass workers suffer from dyspepsia, loss of appetite, gastrointestinal catarrh, vomiting, metallic taste, thirst, constipation, nervousness, oppression, and cold. Among French writers, Bouchut has seen the same symptoms among workers in oxide of zinc. Blaudet also accepts zinc as the causative factor.

I have been unable to find the nervous effects of brass poisoning reported by some English authorities, and which are attributed to copper, and I must accentuate the fact that in poor quality metal, lead is present in considerable quantity, and probably arsenic as well. With this latter view Chevallier

coincides. Suckling has seen nervous disorders induced by brass working; he cites two cases and reports two more of ataxia in brass workers, and thinks that unless a peripheral neuritis, due to this cause be borne in mind, locomotor ataxia will be diagnosed. The symptoms quoted by him are—ataxia, loss of reflexes, pain, tenderness, numbness, paralysis, green hair, sweat, and teeth. Hogben has seen cases of nervous disorders in copper and brass workers but does not feel sure they are due to this work. Arlidge thinks much more clinical observation is necessary to connect the symptoms of multiple neuritis with the occupation.

On the other hand, Schlockow, in describing the zinc workers of Silesia, says they suffer from pallor, bronchial catarrh, gastric derangement, pains in the legs, feelings of constriction, tremor, paralysis. of the upper extremities, and ataxia (pseudo tabes); after death they show sclerosis of the anterior and lateral columns of the spinal cord.

Among workers in zinc oxide from ore which contains but a small percentage of lead and arsenic I have not been able to find cases of paralysis.

A source of ill health which cannot be ignored is to be found in the great and sudden changes in temperature. From working over hot furnaces, the men go into the open air to cool off; even in winter they come from the furnace rooms into the open air perspiring profusely, clad only in shirt and trousers, the former open at the neck. In summer the temperature of some of the furnace rooms reaches 120° F., and heat prostrations are not uncommon; this is more so in copper and zinc works than it is in brass foundries, for the furnaces are much larger and the heat is greater.

I have obtained the following blood specimens from smelters of refined copper, and of good quality brass:

| | COPPER | | | BRASS | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | i | ii | iii | i | ii | iii | iv | v | vi | vii | viii | |
| Polymorph. neutrophiles | 59. | 55. | 60. | 70. | 68. | 68. | 56. | 59. | 52. | 58. | 56. | |
| Lymphocytes... | 12. | 17. | 20. | 11. | 7.5 | 6. | 13. | 12. | 10. | 21. | 11. | |
| Large mononuclear leucocytes | 21. | 22. | 19. | 17. | 23. | 21. | 24. | 25. | 30. | 19. | 20. | |
| Eosinophiles ... | 1.8 | 3.5 | .6 | 2. | 1. | 3. | 3. | 2. | 2. | 1. | 2. | |
| Transitional forms | 6. | 2. | 4. | ... | 1. | 2. | 3. | 2. | 6. | 1. | 11. | |

No basophilic granulation of the cells was present to any extent.

The specimens all show an increase in the large mononuclear leucocytes; the specimens were taken at random among the workmen.

*Summary.*—Copper smelting is a dangerous occupation, because of the tremendous amount of dust which rises from the fire when feeding the furnace, and men cannot work long in this position; they contract both the lighter and more severe pulmonary diseases; where the ore runs a high percentage of lead and arsenic, cases of severe poisoning occur and paralyses are not uncommon.

As zinc occurs with sulphur, lead, and arsenic as impurities, the effects of zinc roasting is about similar to that of copper, with the addition of the so-called ague seizure and its accompanying symptoms.

The chills occurring in brass workers are due to zinc for the following reasons: Oxide of copper is not volatile, while zinc oxide is very readily volatile; chills do not occur among melters of pure copper; in the roasting of zinc ore the men suffer from similar symptoms; chills do not occur while making bronze, which contains much copper and but little zinc; workers in zinc oxide suffer from a like complaint.

The respiratory influence of brass-making in the course of time is bad, but depends largely upon the means of ventilation; the respiratory effect of polishing is not bad, providing the workers are protected by the proper suction apparatus; under poor conditions both occupations can lead to serious results. Working over the sulphuric acid bath is the most dangerous part of the trade. Sand blasting is detrimental to health, corresponding to the dangers of stone cutting.

The gastrointestinal effects are seen more particularly in filers and polishers, who transfer dust and filings to their mouths. Copper here plays a great factor as do lead and arsenic in metal of poor quality.

Nervous results, due to copper and zinc, I have not been able to prove satisfactorily; those reported by the English authorities as due to copper are open to question. Schlockow reports cases among zinc workers with sclerosis of the anterior and lateral columns of the cord. These I have been unable to verify among workers in zinc ore that contains but a small amount of lead and arsenic.

Muscular and joint pains complained of by metal founders can be ascribed to the changes of temperature to which they are subjected.

Heat prostrations occur in hot weather.

Alcohol must be borne in mind when we are looking for bad effects of metallic working.

## RHEUMATISM OF THE FEET.

By LEONARD W. ELY, M.D.,

NEW YORK.

ORTHOPEDIC SURGEON TO THE ROOSEVELT HOSPITAL DISPENSARY, ETC.

Among the patients seeking relief at an orthopedic clinic probably the most frequent complaint is "rheumatism of the feet." Many know they have rheumatism because they have pain, many know it because they have been told so. Many have been treated for their troubles with salves, liniments, and "anti-rheumatic" remedies. Some dust powders in their shoes, some drop in at the obliging shoemaker's and get "plates," some carry a potato in their pocket, or wear a cord about their waists.

The human foot in health and in disease is a most interesting object. Much can be learned from a careful study of it in action and at rest—of its arches, its depressions, its prominences, its shape, its attitude, its feeling, its range of motion. Is it flabby or firm, moist or dry, warm or cold, large or small? Let us begin our task, then, in every instance by asking the patient to remove his shoes and stockings. It is possible that no one has ever asked him to do this before. While he is taking off his stockings we will look at his shoes and see what we can learn from them.

Now, this "rheumatism of the feet" is rather a broad subject, and experience with it teaches that it admits of an extensive classification. The first form of rheumatism we shall consider is not rheumatism at all, but flat foot, weak foot, weak ankles, broken-down foot, pes valgus, pes planus—call it what you will. The usual history that goes with it is that for some reason the foot as a machine has been subjected to a strain which it has not been able to bear. A person who lives in idleness, and who sits most of the time, can deform his feet with shoes to suit his taste, and can in other ways abuse them with impunity, but if he begins to go about a great deal, and uses his feet as walking machines, he is apt to suffer from corns, and to be compelled to adopt some fairly rational form of foot-gear. On the other hand, the patient who suffers from flat foot is usually one whose occupation compels standing; hence the great number of nurses, bar-keepers, waiters, salesmen, policemen, motormen, who seek relief. I say suffer from flat foot, for, as Whitman has pointed out, there is no constant relation between the amount of abduction and flattening, and the symptoms of pain and discomfort. Many have flat feet and do not even know it, but when they adopt an occupation that compels standing, or put on much flesh, or undergo a trauma, such as a sprain or even a contusion, then the machine breaks down, and its owner consults his physician.

The chief symptoms of simple flat foot are pain and weakness, under the malleoli, in the instep, or under the soles. The motions may not be limited. Often the circulation is poor. Often when the patient stands, his feet will be abducted and his arches flattened. This is flat foot. Often there is no deformity. This is "flat foot" with no flattening, or, better, weak foot. Another form of flat foot differs from the last in that the foot is fixed in the abducted posture. Abduction cannot be done except with the use of more or less force, and causes great pain. The foot is held rigidly in its abnormal position by the spasm of the foot muscles, and the arches are flattened. The patient hobbles along with knees bent and toes turned out, and is practically crippled. The least roughness in the pavement is carefully avoided. The rigidity, stiffness, and spasm are so great that the uninitiated talk of bone disease and of ankylosis. Dave Warfield, in his old impersonations at Weber & Fields', used to give an excellent picture of this complaint, and numerous examples of it can be found among the waiters in fashionable restaurants.

Another form of "rheumatism" is anterior metatarsalgia or Morton's toe. This is a neuralgia or neuritis affecting one of the metatarsal nerves, usually that between the third and fourth toes. The pain is distinctly located, often runs up the foot and leg, and can easily be brought out by pressure over the affected nerve, or by lateral compression of the metatarsus. It comes usually in paroxysms, and often compels the patient to sit down in the street and remove her shoe. It usually occurs in women, especially in the well-to-do, often in neurotics, sometimes in the gouty. Sometimes the transverse arch under the ball of the foot will be broken down, and the heads of the metatarsals will be covered with callosities.

Gonorrheal arthritis or periarthritis of the ankle has often been observed. It causes great pain, swelling, local temperature and restriction of motion. Often it cannot be distinguished from tuberculosis at the first examination, but the history and the condition of the urethra will help us. The exudation is more apt to be of the plastic type in gonorrhea, the muscular spasm is less, and other joints are more liable to invasion.

To a form of gonorrheal infection which I have never seen discribed, and which I am not able myself to describe accurately, I have given the name of "gonorrheal foot." It is characterized by extreme sensiteiveness, usually in the soles. The pain and sensitiveness seem out of all proportion to any objective symptoms. Often the circulation is poor. A history of a comparatively recent infection by the coccus of Neisser can be obtained, and the urethra will be found affected. These feet have something about them that immediately makes one suspicious, but further than the extreme sensitiveness and the fact that the patients walk as if they were treading on eggs, I cannot tell exactly what it is. Even the pathology is a matter of doubt, for the condition is not one to justify an operation, and the diagnosis is a mere matter of empiricism.

Two cases of "rheumatism" I have seen which were distinctly hysterical. The first defied all local treatment and yielded finally to suggestion. The second simulated flat foot with great rigidity and spasm. The deformity disappeared promptly on the administration of an anesthetic. The patient drifted away after a while, and a year or so later I stumbled on her in another clinic, where her complaint was diagnosed as a tuberculosis of several joints. An hysterical foot is a great rarity. These two cases are curiosities. Never should the diagnosis be made unless we are driven into it.

Probably no form of "rheumatism of the feet" has been the cause of more humiliating and disastrous mistakes than tuberculosis of the ankle and tarsus. Usually occurring in a child, the first symptoms are limp and localized pain. Then come the pain at night, the swelling gradually growing larger, the muscular spasm and limitation of motion, and the deformity. All this time salves and anti-rheumatic remedies are being used, until at last the abscess forms, and our mistake stares us in the face. Any circumscribed, persistent, painful swelling in the foot, especially of a child, is to be viewed with extreme suspicion, especially if it be accompanied by limitation of motion. Tuberculosis of the os calcis often affects no joint, and the diagnosis must be made from the sensitive swelling over the bone, which usually fluctuates. If we avoid even the mention of the word rheumatism, we shall probably arrive at the true nature of the process. We may be in doubt as to the exact location of that process, but this is unimportant. The treatment is the same for tuberculosis of any of the tarsal bones or joints. From a tenosynovitis we differentiate it by its failure to follow the course of a tendon, and often by the fact that it may be seen to lie beneath the tendons.

An occasional cause of "rheumatism" is fracture, either a Potts' fracture or a fracture of the tarsal bones. A man who has had a Potts' fracture is confined to his bed with his joint in a bad position. The machine is distinctly out of gear, and when its owner gets up and begins to go about, he suffers from "rheumatism." Inspection reveals the site of the old fracture, the widened mortise of the ankle, the equinus, the valgus. Proper dorsal flexion, inversion and adduction are impossible. The man limps and is incapacitated for work. The foot feels worse, of course, in damp weather, so again we think we must have a rheumatism, but again it is a rheumatism that will never yield to rheumatic remedies.

The frequency of fracture of the tarsal bones is just beginning to be recognized, especially fracture of the calcaneum and astragalus. The history of this injury is characteristic, almost diagnostic. A man falls from a height and lands on his feet. He is *carried* home and is laid up in bed with great swell-

ing and pain in his heels and ankles for several weeks. He then gets up, and suffers from "rheumatism" at the seat of fracture. Inspection shows a peculiar abduction of the heels, entirely different from the abduction at the mediotarsal joint found in flat foot. The external tuberosity of the os calcis will be nearer the malleolus than in a sound foot, the normal concavity under the external malleolus will be absent, and the internal malleolus will be prominent. In fracture of the os calcis we shall get thickening and sensitiveness at the seat of fracture, while in fracture of the astragalus there will often be a limitation of motion at the ankle joint.

A form of rheumatism without definite pathology consists of pain in the feet and legs, vague, indefinite, elusive. It occurs in neurotic, constipated males, and yields to the application of the cautery.

Somewhat similar are the pains of late syphilis. Here the diagnosis must be made on the general condition, rarely on the history on account of the well-known mendacity of patients at this stage of their disease.

Rather an annoying experience is to treat a man's feet for rheumatism, or perhaps for flattening and weakness, and then later to have one's attention called to the absent knee-jerk, the Romberg symptom, and the Argyll-Robertson pupil. A few falls like this will teach us that the foot, while it is itself a machine, is only a part of a larger machine.

We might be inclined for a while to regard an anterior poliomyelitis in a young child as rheumatism, if we admitted the possibility of rheumatism of a joint at that age, until the paralysis set us straight.

True gout, gouty arthritis in the great toe, is too well known to need description by me. Here, at last, if rheumatism is gout and gout rheumatism, we are within the scope of our subject.

Acute articular rheumatism occurs in the feet and ankles. Its constitutional symptoms, its pyrexia, its fleeting nature will mark it clearly. *Acute articular rheumatism never leaves behind it a damaged joint.* This fact should be held firmly in mind.

If we have made our diagnosis, if we have put our foot firmly into that path of "rheumatism" in which it belongs, a great part of our task is done. A good textbook will often help us for the rest, but not always. No mechanic can mend a machine with knowledge acquired in textbooks. He must use his intelligence, his common sense. Usually the tools we need will be few—some zinc oxide plaster, some plaster-of-Paris, and a few drugs. Often we shall need a brace-maker and a shoemaker who will do just as we tell them. In using adhesive plaster we must avoid strapping all feet according to some one method, but must make up our mind what we wish to accomplish, and strap the foot accordingly. Hence the fallacy of asking: "How do you strap an ankle?" A word as to plaster bandages. They are best made with dental plaster, and Vigilant brand of crinoline. They should be rolled loosely, and before using should be set on end in plain warm water until they are wet through. Good plaster bandages cannot be bought in the shops, and unless we have good ones we will be apt to condemn the use of plaster as a dressing or splint. Good casting plaster can be bought for $2 per barrel. A word also as to the difference between a plaster bandage or dressing, and a plaster cast. If we encase a limb in plaster, we say that we put it up in plaster, or that we put on a plaster bandage. If we make a counterfeit presentment of a limb we call that a cast. We never "put a cast" on a leg.

Simple Weak Foot.—My routine treatment for this is as follows: With the foot in adduction and dorsal flexion, a strip of adhesive plaster 2 or 2½ inches wide is started from the external malleolus, and is carried under the foot and up the inside of the leg almost to the knee. This is reinforced by a similar strip about ½ inch anterior to the first. The ankle is then strapped with a 1 inch figure-of-eight, each turn overlapping the preceding by about ½ inch. The strapping goes down the outer side of the foot, under the sole, up the inner side, around the leg and down again. The whole is then covered with a snugly fitting gauze bandage. In dispensary practice the patient is instructed to buy himself a good stout pair of broad-soled laced boots, and is given a card to our shoemaker instructing him to build them up ¼ inch on the inside, that is, on the inner side of the exterior of the shoe. In private practice the patient goes to a shoemaker who has been instructed exactly how to build his lasts, and who submits them to us for inspection before building the boots. No shoemaker knows how to make shoes, unless he has been shown. He must be told just what to do, and must be compelled to do it. We cannot shift the responsibility on his shoulders. If anything goes wrong, it is our fault. The patient is taught to practise voluntary adduction and dorsal flexion, to turn his feet directly forward in standing and in walking, and to go through the exercise of raising himself on his toes and then, throwing out his ankles, to come down on the outer border of his feet to his heels again. Running, walking, bicycling, and dancing are good, skating is bad. Often these simple methods will suffice. If not, we must make casts of the feet, and from these have some form of brace made, preferably of the Whitman type.

For the form of weak foot often found in very stout people, characterized by pain in the sole, and due to stretching of the plantar fascia, I start the broad strapping well up on the outside of the leg, carry it tightly under the instep, and then pull it taut up the inside. In other words the plantar fascia is "slung" from the calf. The shoe has a very stiff, highly-arched shank; the sole plate is made on the same principle.

In those cases of flat foot characterized by fixed deformity and spasm, the normal range of adduction and dorsal flexion must be regained as a condition precedent to other treatment. The surgeon, sitting in front of the patient, grasps the heel with one hand, *e.g.* the left heel with the left hand, and with the other hand forcibly adducts the front part of the foot. The patient, with his foot in this position of adduction, then flexes and extends it at the ankle. Now let him bend his knee, cross his leg over the other, and take his own left foot by its metatarsus with his right hand. Holding his foot now in strong adduction, his leg steadied by his left hand, he alternately flexes and extends it, at first passively, later, as he becomes accustomed to the exercise, actively. This exercise he practises in all his spare moments until he has made his foot mobile, when the further treatment is as above. In the inveterate cases this treatment will be too severe, or perhaps impossible. Then we anesthetize, twist the foot over, pad it very thickly with cotton batting, and put it up in extreme adduction and dorsal flexion in plaster-of-Paris for about a month. During this time the patient is encouraged to walk in the plaster, provided with large overshoes. When the plaster is removed, we cultivate passive and active motion as before, strap, and apply the Whitman brace.

In sprains of the ankle we use the criss-cross Cotterell strapping; in sprains of other parts of the foot we apply our strapping in such a way as to take the strain off the damaged ligaments.

There is hardly any other form of "rheumatism of the foot" that yields such brilliant results to treat-

ment as anterior metatarsalgia. Sometimes a properly made shoe, arched transversely up in the sole under the heads of the metatarsals, with a flat or "dropped" toe will itself effect a cure. Sometimes a strip of one-inch adhesive plaster, wound around and around the distal heads of the metatarsals, perhaps provided with a beveled button of sole leather just back of the head of the second or third, will help. The most satisfactory treatment is by a steel sole plate, a "metatarsal plate," 18 gauge, made from a trimmed cast, reaching from just behind the heads of the metatarsals to about one-half inch anterior to the back of the heel, and hammered up by the bracemaker just behind the heads of the second and third metatarsals. If the toes are stiff and flexed dorsally they must be limbered up, and active and passive plantar flexion must be cultivated. Rarely, very rarely, will a cutting operation be necessary.

In gonorrheal arthritis and periarthritis the treatment is the same as in other gonorrheal joints. In the so-called gonorrheal foot we support any weak portion with strapping or with braces, and turn our attention to the urethra, for not until this be set in order will the symptoms abate.

In tuberculosis occurring in children the best treatment is by plaster-of-Paris, and by some form of brace, usually the Thomas knee brace, to put the foot at rest and to relieve it of the weight of the body. Any radical cutting operation is to be avoided. In adults conservative treatment is out of place. The sooner the diseased joint is excised the better.

In "rheumatism" following fracture with malposition of the fragments, we must first secure an approximately normal position of the foot if we would relieve the symptoms. Sometimes we can do this by strapping, wrenching, and plaster-of-Paris, sometimes by passive motion and massage. Sometimes we cut the tendo Achillis, refracture, chisel away bone or take out the astragalus. We must work out each case by itself, and by skiagrams and by other means we must try to make out exactly what condition confronts us. No routine methods will do here.

For the pains of late syphilis we use mercury and the iodides. In the earlier stages of anterior poliomyelitis we guard against contractures by passive motion and massage. When the final amount of paralysis has been determined we apply a brace to prevent deformity.

In conclusion it might be said with slight exaggeration that an article on rheumatism of the feet should read like the old book on snakes in Ireland: "There is no rheumatism of the feet." The word rheumatism has suffered much abuse. Almost invariably its use in this connection is a mistake.

451 West End Avenue.

## THE GASES OF THE BODY.

By L. H. WATSON, M.D.,

CHICAGO, ILL.

But slight attention has been paid in medical literature to the gases of the body. Some of these gases are complicated in their composition, and others are simple and uncombined. All animal tissues contain gases. Of these gases some, like oxygen, nitrogen, and carbon dioxide, are essential to our existence; others are waste products, depending upon fermentation and decomposition for their presence in the body. These latter are often a source of much pain and annoyance, while at the same time they complicate the diagnosis of stomach, intestinal, and heart troubles, to the extent of causing a grave prognosis, or at least a hesitating one, when their presence is not understood. Appendicitis, intestinal obstruction and inflammation, ovarian disease, and heart troubles are some of the simulated diseases caused by the presence of gases in the intestinal tract.

Some of these gases are produced within the body, and others are introduced in various ways, until we seem to be, as an old gentleman pithily expressed it, "nothing but a gas factory." Nitrogen, oxygen, carbon dioxide, sulphureted and carbureted hytrogen, and marsh gas are the principal gases we have to deal with. The oxygen gas of the body is furnished by the saliva, the swallowing of atmospheric air, and the air taken into the lungs. In the alveoli of the lungs, where the presence of the oxygen is considerable, the hemoglobin is completely or very nearly, saturated with oxygen. In the tissues where the oxygen diffuses itself, or enters into combination with reducing substances, so that the pressure is diminished, a portion of the combined oxygen is set free by heat, and the pressure rises again. In this way the red blood corpuscles are always surrounded by oxygen under a definite pressure. Thus the balance is maintained, and the store of oxygen is never exhausted.

Direct experiment, physiological chemists tell us, has shown that the partial pressure of oxygen in the surrounding atmosphere may increase threefold, or diminish to one-half, without any disturbance being manifested in the breathing of a mammal. When the pressure is reduced further the frequency of respiration increases. According to Paul Bert, the experience obtained in mountain and balloon ascents is in complete harmony with the results of experiments upon dogs. Dyspnea does not begin until a height of five thousand meters is reached. Human beings live as well in Leadville, or on the elevated plateaus of the Andes, as at the seashore.

The poisonous effect of carbon dioxide depends upon the displacement of the oxygen. It is said that animals devoid of hemoglobin are not influenced in the slightest degree by the presence of carbon dioxide in the air. It was not until Magnus had analyzed the gases of the blood, that it was proved that oxygen passes on to the capillaries and then partially disappears on account of meeting on its way with reducing substances. The quantity of oxygen in lymph and the different body serums is not great.

Another one of the gases we have to consider is carbon dioxide, which enters the body as carbon and leaves it as an end or waste product of metabolism. It is through the vegetable products which are introduced into the body for the purpose of nutrition that the carbon finds its entrance into the tissues. It enters as carbon, or in combination with the lime, soda, and magnesia of plant life, to be decomposed and excreted as carbon dioxide. This is mostly accomplished through the lungs, but partially through the urine and feces as urea.

Carbon dioxide is the largest in volume of all the gases of the body, and the most widely diffused. It is found in the brain, in the lungs, in serous effusions of the body, and in the tissues. Carbonic acid gas has always been regarded with suspicion by both physicians and laymen. It is designated as a poisonous gas, and its presence is deprecated as an unnecessary and hurtful compound, which the body tries to rid itself of by excretion. Modern physiological chemistry, however, takes quite a different view of it. The only way in which carbon dioxide can be considered injurious is as an obstructor of respiration, when the attempt is made to breathe in an atmosphere saturated with carbonic acid gas. Its presence in the body, while caused by metabolic changes, is not that of a poison. The neutralization of the acid chyme by the alkaline carbonates pro-

duces a large amount of carbon dioxide, but this is not its only source. Schierbeck has shown that a part of the carbon dioxide is formed by the mucous membrane of the stomach. The tension of the carbon dioxide in the stomach corresponds to 30 to 40 mm. of mercury in a fasting condition. It increases after the taking of food, independent of the kind of food, and may rise to from 130 to 140 mm. of mercury during digestion. It is also influenced by certain nervous conditions. I have seen the stomach and intestinal tract distended enormously in a few moments during states of excitement, and the distention as quickly disappear, when the excitement was allayed. The curve of carbon dioxide tension in the stomach is the same as the curve of acidity in the different phases of digestion; and Schierbeck has found that this curve is increased by pilocarpine and decreased by nicotine. The large amount of carbon dioxide which is found in the body would seem to be a source of danger from the disturbance which this enormous quantity of gas might be expected to create, from mechanical reasons alone, and much more so were it poisonous in character. But no matter what the amount generated or introduced into the body, it soon diffuses into the tissues and blood, or is returned to the air by excretion from the lungs, bowels, and kidneys, and thus a proper equilibrium is always maintained. It is estimated that from six to eight liters of $CO_2$ are liberated in the intestines alone by neutralization of the acid secretions. We are not at all inconvenienced by this large volume, for its coefficient of absorption is very high.

It has been estimated that the pressure of $CO_2$ is 10 per cent. of an atmosphere. As soon as the bowels contain more than 10 per cent. it diffuses into the tissues and blood. A reciprocal action takes place between the oxygen inspired and the carbon dioxide generated in the body. This change has been called "internal respiration." Its extraordinary diffusibility (only exceeded by that of sulphureted hydrogen) causes a constant ebb and flow in its movements. The increased pressure is indicated by quickened breathing, a more rapid heart beat, and considerable excitement, until the equilibrium is established. In spraying the stomach with $C\ O_2$ I have noticed within ten seconds the breathing is accelerated, the eyes become suffused, and a general condition of exhilaration is observed. The feet and hands, which had been previously cold, become warm, the change from venous to arterial blood is more rapid, and a sense of comfort pervades the body. This is equally the case when taking an effervescing bath at Franzensbad, in Bohemia, where the water is highly charged with $CO_2$. It is quite impossible to remain more than from 8 to 10 minutes in a bath of the water from the Stahlquelle. Even after leaving the bath, one has a sensation of lightness and ease for an hour or more.

Among neurotic patients with stomach troubles the abdomen is often enormously distended with $CO_2$ in a few moments, and is a source of much discomfort and mortification from audible movements in the bowels. The diffusion here is from the blood into the stomach and bowels under the influence of a disturbed nervous condition.

Consumption of oxygen and elimination of carbon dioxide depend upon work. Metabolism is kept at a low point by inactivity of the body, increasing fat formation, through lack of oxygen consumption. It has been stated by some physiological chemists that the greater the weight of the body, the greater the consumption of material. But other things being equal, a small animal of the same species, metabolizes more, relatively. A fat person decomposes less substance per kilo than a lean one. To what extent sex influences metabolism is an unsettled question. Tiegerstedt and Sowdin found that in the young the carbon dioxide elimination per kilo of body weight, as well as per meter of body surface, was considerably greater in males than in females of the same age and weight of body. The difference disappears gradually, and in old age the results are the same. The general amount of $CO_2$ in the blood and serum depends upon bodily activity and metabolism. The maintenance of an even standard is not possible always, but within certain limits is sustained. The pressure rises and falls as the loosely combined $CO_2$ is decomposed or absorbed.

I have referred to "intestinal respiration," this gaseous exchange consists chiefly in that the oxygen passes from the blood in the capillaries to the tissues, while the $CO_2$ passes from the tissues to the blood and serum. This exchange is constant and reciprocal. So long as we have access to an oxygen atmosphere, the volume of $CO_2$ in the body is not only not hurtful but helpful, and it is a question today if life could be maintained were carbonic acid gas not a great factor in the function of combustion constantly going on. The muscle at rest or in action constantly gives off $CO_2$ and we breathe more or less rapidly as the volume increases or diminishes.

The abnormal accumulation of gases in the bowels is quite as painful and more confusing than a stomach distended with gas. Twice in the past year I have known of cases very near to operation through mistaken diagnosis. In one, old adhesions of the bowels were stretched and pulled, until pain and tenderness suggested appendical trouble. In the other, a plain case of flatus, the diagnosis was the same, but the surgeon called upon to operate, being afflicted with a conscience, waited a bit, and the scare was over, with some ludicrous happenings, to the great discomfiture of a well-known clinician.

The long intestinal tract with the various chemical changes occurring, and the existence of decomposition through the agency of microorganisms, offers many natural reasons why most rigid scrutiny should be made in this fertile field for gases before an excathedra utterance is ventured upon.

The large amount of cellulose, which, in the ordinary way of nutrition, passes through the bowels, forms a fruitful cause for flatus. Peas, beans, lentils, cabbage, rye-bread, and oatmeal cake induce large amounts of gas formation. The gases commonly found are carbureted and sulphureted hydrogen and marsh gas. Of oxygen gas and carbon dioxide I have already spoken. The formation of hydrogen and marsh gas is due to the fermentation induced by the different bacilli found in the intestines. In all healthy bodies these gases are found, but when abnormally existing they are due to perversions of function, which favor favorable culture mediums, and facilitate the multiplication of the various bacteria and hyphomycetes.

We have lactic, acetic, and butyric acid fermentations, and the decomposition of fats, proteid matter, and cellulose, to contend with in our study of the gases found in the bowel. There are many intestinal antiseptics in our pharmacopeia, but actual intestinal antisepsis is an impossibility, and will never be realized. The soil for breeding bacteria is too favorable, and the constant introduction of decomposing and fermentable material, as well as the unfavorable conditions arising from stomach and intestinal diseases, render abortive our best efforts to maintain a condition of perfect antisepsis. We can, however, with care in feeding and proper attention to catarrhal and obstructive conditions, modify the

abnormal formation of gases. Meteorism often occurs after abdominal operations, or in peritonitis, due to toxic paralysis of the bowel. Kader has made many experiments in local meteorism. When coils of intestine are strangulated in a moderate degree, that is, if ligatures are placed around the loops of intestines and their mesentery, and if these ligatures are tied sufficiently tight to permit the entrance of arterial blood into arteries and arterioles, the strangulated coil of intestine and mesentery assumes a dark reddish-blue hue. This experiment produces the same conditions in the intestines and mesentery that are met with in pathological states.

Venous statis occurs, and first water and later gases are found in the looped off stricture. Kader found that the development of gas in the coil of intestine between the two occlusions was chiefly due to the disturbance of venous circulation. These conditions exist in volvulus and other occlusions of the bowel.

Phantom tumors are also of this order. I remember distinctly a case of much interest occurring a number of years ago. A lady of fifty or fifty-five years of age had been ill for more than a year with a bowel trouble. Different diagnoses had been made by physicians and surgeons. When called to see the case, I found there had been no movement of the bowels for a week, although powerful cathartics had been used. The patient told me that knots would come up in the bowels, causing excruciating pain. The description was so vague that I paid little attention to it at the time. Mentally I considered the case to be one of occlusion, and an operation indicated. While leaving, I was recalled and witnessed the phenomenon. In different parts of the abdominal wall two or three hard lumps, the size of a child's fist, appeared. They were very firm and incompressible; great distress was evident. This condition lasted for four or five minutes, and then the lumps gradually diffused or disappeared. I was told this occurred a number of times daily. I prescribed strontium bromide in full doses every two hours until four or five doses were taken, and a grain of calomel in divided doses in the evening. Upon my return the next day I learned that five or six copious and extremely offensive stools had been voided. The lumps had only partially returned. The bromide mixture was continued in smaller doses for a week. The bowels became quite regular, the knots did not return, and recovery was rapid. In two weeks the patient ate normal food, gained in weight and strength, made visits, attended entertainments, and seemed practically well. A difficulty occurring about visits to my office, I did not see the case again. I understood the bromide mixture was discontinued. Some months later the trouble recurred, and an operation was advised. The patient died while under the influence of chloroform before the abdomen was opened, and, no autopsy being allowed, absolute knowledge of the cause of the trouble was not obtained. An enterospasm of a neurotic character certainly existed, to what extent this was accompanied by occlusion I have no means of learning, but recent observations by Heidenhain and Schloffer indicate that enterospasm may cause the complete picture of occlusion, when laparotomy shows no obstruction whatever.

Most of the gases of the intestines are formed by putrefaction and fermentation. Carbon dioxide partially so, but suphureted and carbureted hydrogen, as well as methyl mercaptan, almost entirely so. Marsh gas is formed through the fermentation of cellulose, as found by Tapeiner. The proteid decomposition is accomplished through the agency of microorganisms, and almost entirely in the large intestines. The fetid odor of the excrement is largely due to the formation of indol and skatol. These are two products of the aromatic series, and are found in the urine with indican. When the intestinal tract is free from bacteria, as in the meconium of newly-born infants, odor is wanting. Sulphureted hydrogen gives very little trouble in the bowels, carbureted hydrogen and marsh gas much more on account of their low coefficient of absorption. While sulphureted hydrogen does not cause much trouble in the bowels, it does cause many unpleasant symptoms through absorption. Headache, vertigo, and nausea are often present as the result of sulphureted hydrogen generated in large amounts in the bowels. Our efforts should be directed toward lessening the amount of these gases by suggesting a proper diet. The butyric acid fermentation of cellulose, and the carbohydrates is a potent factor in the formation of these gases. Constipation increases the amount of proteid decomposition, while diarrheas, or the frequent use of mineral waters, hasten the passage of food through the intestinal tract so rapidly that the body is not properly nourished; and while relief from gases is accomplished, it is at the expense of nutrition.

100 State Street.

## THE IMPORTANCE OF THE EARLY RECOGNITION OF VALVULAR DISEASE IN CHILDREN.*

By ALBERT EWING CHILDS, M.D.,

NEW YORK.

ASSISTANT ATTENDING PHYSICIAN, CHILDREN'S DEPARTMENT, CORNELL DISPENSARY; PATHOLOGIST TO THE LINCOLN HOSPITAL; MEMBER OF THE BRONX MEDICAL SOCIETY.

Routine physical examination of children is absolutely essential to the appreciation of their ailments. It takes time thoroughly to examine a child, as an examination to be of positive value must be made down to the skin. Many conditions may be overlooked by a superficial examination through clothing, especially cardiac lesions. It is surprising what unlooked-for things a physician will find if he systematically makes a physical examination on his little patients, and by this I do not mean that every patient must be stripped, as is done in hospital work, but the clothing, if not removed, should be so arranged that access to the skin may be had. Nowhere in the four epochs of life, childhood, youth, middle-age and senility, does this routine physical examination apply so strongly as in childhood. The pathology of childhood presents difficulties which cannot be surmounted except by the keenest observation. Very young children cannot tell us anything, and the older ones won't, or if they do their statements are more liable to be misleading than of benefit. Among children there is not the objection to removing the clothing that we frequently have to combat among adults, and it is the physician who gets right down to the bare skin who gets to know children as they should be known. Many times a child with its clothes on may present a picture of fairly good nourishment, but strip it, and a grade of malnutrition may be found that will be surprising.

I have digressed from the title subject more forcibly to emphasize the remarks to follow. Endocarditis may occur as a complication in any of the acute febrile diseases; but it is on the rheumatic form that I shall largely dwell in this paper. Endocarditis in children, more especially the rheumatic form, unfortunately for the little ones, is only rarely recognized in its primary manifestations. Years later

* Read before the Bronx Medical Society, April 12, 1905.

when the damage is irreparable it is discovered either accidentally or when the child is brought for treatment with dyspnea and the train of other symptoms due to broken compensation. Acute inflammatory rheumatism as we see it in adults occurs rarely in children. In adults the disease manifests itself in an arthritis with high fever, swelling and redness of the joints, with extreme tenderness. There is no mistaking the diagnosis, and as we know that the complication to be most dreaded is endocarditis, we are on our guard and watch the heart for signs of its occurrence. The manifestations of rheumatism in children, however, present a very different picture. This statement is meant to apply more especially to children under eight or nine years of age. Instead of the acutely inflamed joints we get a history from the mother, very often only by careful questioning, of wandering pains in the arms or legs, to which little attention was paid. Many times the common term, growing pains, has been the only warning of the endocarditis discovered years later. Some children will complain of pain on handling in the process of dressing or undressing them, but seldom do we find marked joint disturbances. The swelling and redness, if any, is only slight. In some cases there may be a little swelling, but rarely any reddening. One feature that I have noted in particular in older children is that joints with considerable swelling and in which severe pain is complained of may be palpated, using considerable pressure without causing any or but little pain. The same amount of pressure on an adult's joint would cause him to make threats of murder. The joints on moving may or may not be painful.

In order to emphasize more forcibly the many forms that the rheumatic pains and joint manifestations may assume, I have arranged them into four groups. And let me say here that any pain in the extremities of a child, no matter how slight, may mean an accompanying endocarditis. And you will notice that I do not say joint pains, but use the term extremities instead, as the pains are frequently located by a child in the muscles of the calf and down the leg and in the forearm rather than in the joints.

Group I.—Wandering or growing pains. This group I think the most important of all, because, as a rule, little attention is paid to them by the parents, and if a physician is consulted, according to my own experience and from the statements of most of the textbook writers, their significance in the large majority of the cases is not recognized. The history of the pains is confined to as short a period as a week or two. Again they may cover a period of many weeks or months. The pains are not frequent, often only a sticking pain, as children will describe them, once or twice a day. They may occur every day over a definite period or at irregular intervals.

Group II.—In which not much pain is complained of, chiefly stiffness. These children, who have previously been very active, are inclined to lie around, but the parents will tell you that they do not seem to be sick.

Group III.—In which the child will complain of definite joint pains, commonly confined to the knees or ankles, though the shoulders and wrists may be complained of as well. There is no swelling or redness, no pain on pressure over the joint. There may or may not be some slight pain on active or passive motion.

Group IV.—In which there is moderate swelling and redness, with pain often quite severe while at rest or on moving the joints. This group presents the picture of the sub-acute articular rheumatism seen in the adult. This group also, in my experience, is confined usually to children over eight or nine years of age.

Before leaving the subject of rheumatic pains, I want to repeat and to emphasize that every muscular pain, no matter how slight or where located, may mean an associated endocarditis. In spite of the fact that the textbooks warn us that rheumatism occurs in very obscure forms in young children I do not think that the average practitioner appreciates how very obscure its manifestations may be. Dr. Winters, of the Cornell Medical School, to whom I have the honor of being an assistant, puts particular emphasis on the many obscure manifestations of rheumatism in children. He taught me that many times the disease will show itself only by a child's complaining of a little sore throat or pain on swallowing. On examining the throat a little redness may be seen, but many times nothing. There is only pain on swallowing. We have then rheumatism of the muscles of deglutition. Again the most trivial stiffness, with or without pain in the muscles of the neck or along the tendon sheaths, may be the only warning we have. And to repeat what I said in the early part of my paper many children will not complain of any pain or stiffness or anything at all except some slight soreness on handling the muscles while dressing or undressing them. And finally, I want to say that I have had many cases of endocarditis in children at the Cornell Clinic in which by the most careful and exhaustive questioning absolutely no history of rheumatism in any of its manifestations could be obtained. From what I have seen of rheumatic endocarditis I believe that it is possible for the endocarditis to be the only manifestation of the disease, though the cases are certainly rare.

*Joints Involved.*—The joints involved are usually those of the ankle and knee, less often those of the shoulder, wrist, and elbow in the order named.

*The Temperature and Pulse as a Means of Diagnosis.*—Early in a case of rheumatic endocarditis the temperature and pulse often furnish with the indefinite joint pains a key to the condition before the murmur develops. The pulse rate will be found in the neighborhood of 120, or even higher, while the temperature will be comparatively low, 100° to 101° or 102°. A much higher temperature may be had, but I am speaking now of the majority of the cases. If seen after the first week the temperature is found very close to normal, but with the pulse still very rapid. In other words a great disproportion will be found between the height of the fever and the pulse rate. A rapid pulse from nervousness must not be mistaken for one due to disease of the heart. It is wellnigh impossible to say sometimes whether the rapid heart action is due to excitement or disease. A child's pulse that is perfectly normal, on the slightest provocation will become often very rapid. On the other hand it will as quickly slow down when the child's mind becomes at rest. By sitting quietly beside the patient and distracting his attention by talking to some one else in the room, as a rule, the variations of a pulse due to nervousness can be readily detected. In some cases in children of a marked nervous temperament, however, it will be found almost impossible at the time to interpret positively the cause of the rapid heart action.

The examination of the heart by palpation and percussion is usually negative. This statement is meant to be applied only to cases within the first week, during which period cardiac enlargement of any appreciable degree is rarely present. The apex is usually found within normal limits, and a thrill may or may not be felt.

I wish to say here a few words as to the relation of the heart to the chest wall in children without a

knowledge of which many cases of cardiac enlargement will be made out that do not exist. In young children the heart is placed somewhat higher and occupies a position a little nearer the horizontal than in the adult. The apex is therefore higher and farther to the left. Up to the ninth year the apex is found in or near the mammary line. After the thirteenth year it is found, under normal conditions, well within that line. In infants the apex beat is difficult of detection, but in a child it is more readily located than in an adult. Up to the seventh year it is found with about equal frequency in the fourth and fifth intercostal spaces. After the seventh year it is, as a rule, found in the fifth space, occasionally in the fourth. After the thirteenth year it is always, when normal, found in the fifth space. In deformities of the chest the apex beat may be displaced and found in an abnormal position. Both the area of relative and absolute cardiac dullness in young children is proportionately larger than in adults. Unless this is borne in mind a heart may be considered enlarged when it is of really normal size. The full appreciation and understanding of the relation of the heart to the chest wall in children is absolutely essential to the correct interpretation of the findings of an examination of the heart.

*The Murmur.*—On the third or fourth day, sometimes later, the murmur develops at the apex. It is usually systolic in time, and soft and blowing in character. At first it is localized at or near the apex, but sooner or later it is carried to the left into the axilla and heard behind at the angle of the scapula if the valvular lesion is to be one of mitral regurgitation, which the large majority of these cases turn out to be. In these cases of mitral regurgitation an accentuation of the pulmonic second sound is always heard. If the valvular lesion is to be one of mitral stenosis, the murmur which is presystolic in time remains localized between the apex and the ensiform cartilage. With the stenotic murmur a purring thrill may or may not be felt. Primary valvular lesions at the aortic valves are so uncommon that I will not go into them. The murmur of acute endocarditis must not be confounded with functional or anemic murmurs, that are so frequently heard in the acute febrile diseases. Both commonly occur at the base rather than the apex, and their area of transmission is limited. They also vary much in intensity, and may be well marked at one time and very faint or barely audible at another. Pericarditis is to be distinguished by a double murmur, which is also heard, as a rule, at the base of the heart. The sound is rubbing in character rather than blowing.

A leucocytosis is always found in acute endocarditis and is of considerable aid sometimes in helping towards making a diagnosis in an obscure case. We see cases where it is difficult to decide whether the rapid heart action is due to functional disturbance or inflammation of the heart, where there is a little fever of possibly only one-half or one degree, and with a murmur that does not present the typical characteristics of acute valvular disease. If an examination of the blood shows a well-marked increase in the leucocytes and we can exclude other causes of the leucocytosis it favors very much a possible endocarditis.

*Diagnosis.*—It is on the diagnosis of endocarditis in children that this paper has been written, and this is the one predominating feature that I wish to stand out, to the exclusion of all others. The statements I have previously made have been but the means towards an end. All matter except such as seemed to me to bear on that very important factor diagnosis I have endeavored to exclude. In order to make this diagnosis the heart must be followed in rheumatism, bearing in mind the obscure form that the disease assumes in young children. In chorea, in which it is so frequently a complication, and in all the acute febrile diseases, particularly those of obscure origin, careful observation of the heart is also necessary.

*Résumé.*—When I was asked to write a paper for this society the subject of endocarditis in children was the first to come to mind, because these cases have always had a peculiar sadness for me. I have a great love for children, and the realization of how many of these cases do not receive the benefit of treatment, owing to the fact that they are not recognized, led me to begin to formulate a paper some time ago. A diagnosis in these cases certainly does not mean that we can save the heart from permanent damage. Very mild cases occasionally do leave what, as far as we can make out by the means of examination at our disposal, is an apparently normal heart. But in the vast majority of cases, however, some evidence of damage to the valves remains in spite of all treatment. Nevertheless, I claim that if the case is recognized and receives rest with other treatment a great amount of damage may be avoided. And by damage I do not mean so much the saving of the valves as the heart muscle. Certainly with an overacting inflamed heart absolute rest in bed does much towards saving the heart muscle and valve segments by avoiding unnecessary strain on them. The same heart in a child running about, by the sudden strain put on it by overexertion stands a most excellent chance of becoming considerably enlarged, or rarely, in the primary cases, acutely dilated. Following the acute stage the great danger is failure of compensation. This only rarely occurs in the primary attack. The three common factors causing failure of compensation are anemia, impaired nutrition, and overexertion. In all the acute febrile diseases there is the same danger. Here again diagnosis comes in. The anemia and impaired nutrition call for treatment, and if the child's parents have been acquainted with the fact that the child has a diseased heart, the future of which depends to a great degree on the general health being kept as near par as possible, the tendency will be to have the case looked after. Otherwise the anemia and bad nutrition are allowed to run along until, when finally brought for treatment, a greatly dilated heart may be found. All those of us who have followed many of these cases know how rapidly the anemia develops and the nutrition suffers, and we know how much can be done to combat it by tonics, such as cod liver oil and iron, by guarding against constipation and indigestion, by regulating the diet, and in many other ways helping towards keeping the child in general good health. These cases in which marked enlargement or acute dilatation have occurred are the sad cases, for they hold out a bad prognosis at the best. It is really the condition of the heart muscle that counts most in prognosis in valvular disease. And if we expect the heart muscle by hypertrophy to compensate for some valve defect then we must do all in our power to give it strength by nourishing it and giving it rest when it shows that it is getting tired. We must try not to let it get to the point of broken compensation, because broken compensation means each time it occurs a weak heart muscle with less and less recuperative power.

A heart with a valvular lesion, but which is within normal limits, while not favorable to longevity, may carry a patient through a fairly long and active life. On the other hand a heart muscle which has been weakened by dilatation certainly does in most cases mean a short life. The plea that I make for these cases is not of cure, but that we take heed of the many indefinite manifestations of endocarditis in

children and make a diagnosis early. By so doing give the little ones all the chance they can have by putting the heart under as favorable conditions as possible.

In conclusion I am going to give my definition of rheumatic endocarditis in children, which, if kept in mind, will do much towards the recognition of these cases.

Rheumatic endocarditis is an inflammation of the lining membrane of the heart commonly confined to the valves, manifested by stiffness or pain in the joints or tendon sheaths, or in any of the muscles of the body, from the most trivial or obscure form to a well-marked arthritis; by rapid heart action without regard to intermittency or irregularity; by a low grade of fever, oftentimes but a half degree; by a soft blowing, usually systolic, murmur at the apex of the heart, and by the presence of a well-marked leucocytosis.

## A CASE OF FIBROMA OF THE ILEUM, PRODUCING OBSTRUCTION BY INVAGINATION; ENTEROTOMY; RECOVERY.

### WITH A BRIEF CONSIDERATION OF BENIGN GROWTHS OF THE INTESTINES, AND METHODS OF OPERATING.*

H. A. ROYSTER, A.B., M.D.,

RALEIGH, N. C.

PROFESSOR OF GYNECOLOGY AND DEAN OF THE FACULTY, MEDICAL DEPARTMENT, UNIVERSITY OF NORTH CAROLINA AT RALEIGH; GYNECOLOGIST TO REX HOSPITAL; SURGEON-IN-CHIEF, ST. AGNES HOSPITAL; SURGEON TO THE SOUTHERN RAILWAY.

Benign tumors of the intestines are by no means uncommon, and yet they are discovered rarely enough to justify reports of instances in which they cause serious symptoms. They seldom give rise to intestinal obstruction except from invagination due to their weight. The classification of Leichtenstern, as given by Senn, divides them into fibromata, myomata, submucous lipomata, and mucous polypi. The same authority states that the rectum (including the sigmoid flexure) is the most frequent seat, and the ileum next, while the duodenum and ileocecal regon are singularly free from benign growths. According to Richard Douglas of Nashville, Tenn., these tumors may be solid or cystic. The former are adenomata, fibromata, lipomata, and nevoids; he considers the adenomata to be the most common of all. The structure of benign growths of the bowel differs in no wise from that of the same kind of tumors in other parts of the body. It is likely, however, that, in the absence of careful microscopic examinations, some of them will be designated as benign, when they are really undergoing malignant degeneration, and it must be kept in mind that carcinoma is the most frequent form of intestinal tumor.

The following is the only case of benign growth of the intestines which I have encountered:

On January 8, 1905, Mr. R. R. S., aged 42, was referred to me by Dr. R. W. Palmer of Gulf, N. C. A brief history elicited at the time of his admission to Rex Hospital gave the following information: He has usually been healthy, and is free from any hereditary disease. In his youth he had intermittent malaria, and, sixteen years ago, typhoid fever. His present illness dates back as far as six months, when he began to have occasional attacks of indigestion and sometimes vomited his food. It was in the early part of September, 1904, about four months ago, that marked symptoms developed. He first had intense pain in the left iliac region, lasting one to two hours. These paroxysms recurred every week or so, becoming more severe and finally almost continuous. For the past month he has not been free from suffering for any considerable period. His bowels have been habitually constipated, and the evacuations are always small in size. Mucus has often been passed, but never any blood. He has lost weight, but does not know how much. For four days his bowels have not moved, and for three days he has been vomiting stercoraceous material at frequent intervals.

The temperature was 97.6 degrees, pulse 100. The abdomen was slightly distended. There was dullness over the descending colon and the sigmoid flexure, while to the inner side of this appeared a mass as large as the fist, which was somewhat movable. The pain seemed to be chiefly in the epigastric region. Fecal vomiting still continued. The blood showed 4,700,000 red and 13,600 white cells; the hemoglobin was 70 per cent. For the purpose of relieving the fecal impaction, which was obviously present, whatever else might be the primary cause of the intestinal obstruction, orders were given, following my usual custom, to administer hyoscine hydrobromate hypodermically in 1/100 grain doses every four hours, and a high enema consisting of one ounce of alum to a quart of water immediately after the second dose of hyoscine. The drug was not well borne and had to be discontinued, but the enemas were very effectual and, after three had been given, followed by an ounce of castor oil, the patient seemed comfortable. The next day, January 9, all traces of the impaction had disappeared and the mass before mentioned was more easily made out. It was much smaller and more movable. A diagnosis of tumor of the small intestine, possibly malignant, was made and consent given to operate.

On January 10, 1905, under ether anesthesia, an incision was made in the left semilunar line, its center being at the umbilicus. The mass was felt below and readily brought up. It was a portion of small intestine (ileum), invaginated and twisted, so that it appeared to be tied in a knot. Unfolding this without difficulty, a tumor was discovered in the lumen of the bowel. Through a one-inch longitudinal incision on the free border of the intestine the tumor was delivered. It was spherical, smooth, of the size of a large walnut and pedunculated, arising from the submucous coat near the mesenteric attachment. An elliptical incision was made around the base of the pedicle, the growth cut away and the mucosa united with a continuous suture of fine silk. The bowel incision was closed by three rows of continuous sutures of fine silk, one in each coat, and an extra interrupted Lembert stitch on the peritoneal coat. The abdomen was closed without drainage and the patient made an uneventful recovery. Histological examination of the tumor proved it to be a pure fibroma.

The questions at issue in the management of such a case are, first, the diagnosis; second, the necessity for resection and anastomosis; third, the direction of the incision in the enterotomy, and, fourth, the method of excising the tumor and closing the intestinal wound.

In this particular instance there could hardly be a doubt but that the bowel was obstructed by a neoplasm. The history pointed strongly to the evidence of a progressive growth; the symptoms showed intermittent periods of partial obstruction and a mass was present, even after evacuation of the bowels by the preparatory treatment. These signs do not ob-

*Read before the Florida Medical Association, April 20, 1905.

tain in acute obstruction from other causes. An important matter would be the recognition of the character of the growth before operation, a difficult thing to do. There was some reason for suspecting malignant disease in this patient, and such tumors are much more frequent than innocent fibroids. And yet, if this suspicion had controlled the situation, the man might still be a sufferer or would not now be alive and well. Too often patients are denied the privilege of an exploratory incision because of the assumption that a certain growth is cancer. "Seeing is believing."

Many cases of benign tumor of the intestine demand the removal of a more or less extensive section of the gut with anastomosis of the severed ends. This depends largely upon the condition of the bowel adjacent to the growth. Watson, of Boston, reported last year a fibroadenoma of the ileum, which required resection of fourteen inches of the intestine. He found the intestinal wall inflamed and thickened for twelve inches above the seat of the tumor and the mesentery hypertrophied, with its glands enlarged and indurated. In my case the bowel was perfectly normal except for thickening at the pedicle, and the usual dark discoloration of the invaginated portion, which quickly returned to its natural appearance after being released. Such matters are to be determined upon the same principles which guide us in operating for ileus from whatever cause. If the growth is thought to be malignant the proper procedure is either a resection or enterostomy; if it is benign, enterotomy is the course to pursue. It stands to reason that opening the bowel by a small incision and closing it securely is much more easily and quickly done than an anastomosis, and in the hands of the average surgeon is a safer operation.

My only reason for referring to the direction of the incision in enterotomy is to quote a suggestion of Senn, to which my attention has been called, viz.: that "the visceral incision should always be made transversely, and never in the long axis of the bowel, as is usually recommended, because transverse wounds can be more readily sutured than longitudinal wounds, and the operation is less liable to be followed by stenosis of the bowel." In future cases it will be my purpose to apply this method. The only possible disadvantage may be that it would not furnish as much room for working. Fenger in 1894 removed a myoma from the ileum through a longitudinal incision aided by an additional transverse one.

The plan practiced here of making an elliptical incision around the pedicle through the bowel mucosa, lifting the tumor out of its bed and smoothly stitching the mucous membrane over the depression is offered as the best possible procedure. Nowhere has it been seen in any textbooks consulted, nor did it occur to the writer until just at the moment it was put into effect. Surely such a method is far superior to the usual way of transfixing the pedicle, tying both halves separately and excising the tumor at a safe distance from the ligatures. (Senn.)

Closure of the bowel wound after the manner above described lends itself peculiarly to this class of cases. By suturing each layer separately and then adding an extra Lembert stitch outside, there is obtained a secure fastening of the slit with the least possible chance that contraction will supervene. In the ordinary closing of intestinal openings the edges are rolled in more or less at the expense of the lumen, as the peritoneal surfaces are brought broadly in contact, and every opportunity is offered for stenosis.

**Congenital Tuberculosis.**—Martha Wollstein reports the case of a woman who died of advanced tuberculosis six days after the birth of a male child in the eighth month of pregnancy. Microscopical examination, according to the writer, showed the uterine lining to have the structure of the decidua at term. At many points cheesy degeneration had occurred throughout its entire thickness, extending into the muscular coat to an irregularly varying depth. Small tubercles with cheesy centers were scattered throughout the middle and inner muscular coats, and were found even at some distance from the cheesy endometrium. Tubercle bacilli were demonstrated in the cheesy areas and also in dicidual sinuses, which were not adjacent to a cheesy mass. Macroscopically the placenta showed a triangular area of 5 x 7 cm., with its base at the placental margin, and its apex near the insertion of the cord; this section was yellow in color, soft in consistence, suggesting cheesy material. The agglutination thrombi had destroyed the syncytium in certain places, while in no section were the epithelial cells affected over a villus whose adjacent spaces were empty or filled with normal blood cells or with fibrinous masses. The case here described illustrates the intervillous chorionic localization of tubercle bacilli with secondary involvement of the villus stroma. Where fibrinous masses came in contact with the villus, the covering epithelial cells were wanting, although immediately beyond the point of contact they were present. This is an interesting point in relation to the question as to whether or not a normal syncytium is an efficient bacterial filter affording a protection to the fetus. The umbilical cord showed no tuberculosis, either microscopically or macroscopically. Neither were tubercle bacilli found in the vessels of the cord in the sections. Tubercle bacilli were found to be abundant in smears from the endometrium. The writer, in summing up the pathology of this case, believes that we may assume that the basal decidua was first affected, the tubercle bacilli traveling from the decidual sinuses to the covering of the villi, localizing there and causing thrombi in the adjacent intervillous spaces with destruction of the syncytium, entering the villous stroma, and finally reaching the chorion. It may be argued that the fetus was infected comparatively late—just before birth—this belief being founded upon the early stage of the tubercles in the child which lived for nineteen days. Tubercle bacilli were found in the liver and spleen of the child. Tubercles were also found in the lung and in the kidneys.—*Archives of Pediatrics.*

**Prostatectomy in an Old Man 77 Years of Age.**—Gayet cites the history of this case in order to show the excellent results that may be obtained by prostatectomy in individuals of advanced age, for it is well known that old age has been placed in the front rank of contraindications to this operation. This patient had enjoyed good health up to 1903, but at that time certain symptoms developed which pointed to trouble with the prostate. Crises of retention occurred, and the patient was obliged to submit to regular catheterization. Still later there was absolute retention and great difficulty was experienced in introducing the catheter; from that time the patient was a constant sufferer; the urine was murky, and sometimes bloody; the patient was obese but pale. Local examination determined phimosis, which made catheterization very troublesome. The purulent urine, after filtration, showed albumin and casts, and there was edema of the legs. Circumcision was practised and a catheter was inserted, through which regular lavage was given, but the patient's condition grew worse. The operation of prostatectomy was then performed. The prostate was the size of a turkey-egg, and was hard and fibrous. The patient was dismissed five weeks after his operation with a small perineal fistula. His general condition was entirely changed; albumin had entirely disappeared. It is now seven months since the operation. Micturition is accomplished voluntarily; there is still slight daily incontinence, but it is steadily decreasing. The writer thinks that the old men should not be deprived of the benefits of this operation.—*La Médecine Moderne.*

# MEDICAL RECORD.

*A Weekly Journal of Medicine and Surgery.*

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, August 5, 1905.

## THE NEW ORLEANS EXPERIMENT.

PUTTING aside for the moment the human misery and economic waste of the epidemic now afflicting New Orleans, the situation is one of intense interest to students of medical science. The mosquito theory of yellow fever transmission is on trial, and upon the result of the efforts now being made by the sanitary officials in the city to stem the epidemic by attacking the mosquito depends the present acceptance or rejection of this theory as a practical working basis in the warfare against yellow fever. The New Orleans authorities have adopted the theory frankly and are working along the lines it indicates in their endeavors to arrest the spread of the disease. Mayor Behrman on Saturday last issued a statement in which he said: "The mosquito theory is accepted by our physicians and laymen alike, and there is nothing remaining to be done but to fight the mosquitos, which is being done by oiling the gutters and screening and oiling the cisterns. . . . We have the situation so thoroughly in hand that we believe we will shortly convince the outside world that by working on the mosquito theory, yellow fever will be entirely robbed of all its perils. . . . This is a fight wholly against the stegomyia fasciata mosquito."

This was a bold statement to be made at a time when the number of cases was increasing and new foci of infection were being discovered daily, but we believe it will be justified by the result. The truth of the theory, it is generally believed by the medical world, was demonstrated experimentally and practically in Havana; and, in the face of the mighty sanitary revolution there effected, objections based upon the unexplained facts of old-time epidemics in Philadelphia and other northern cities, where the stegomyia mosquito does not habitually flourish, have but little force. It is more reasonable to explain these epidemics on the supposition of an importation of the fever-bearing insect than it is to explain the facts of Havana's riddance on any but the mosquito theory.

If New Orleans should succeed in arresting the progress of the epidemic before the advent of cool weather, by oiling her drains, screening her cisterns, and barring mosquitos from the sick, the lesson would be a grand one, and its teaching would be well worth, in view of future good, the loss of life and property which it cost. There would, of course, still be skeptics, the fear-shaken Governor of Mississippi might even then continue his embargo on hardware from infected districts, but men of intelligence a little above this grade, with minds sufficiently broad to recognize facts, would be forced to admit the finality of the demonstration. Thereafter the health officers of any southern city in which yellow fever should gain more than a temporary foothold would be judged incompetent or neglectful of their plain duty.

The task calling for accomplishment by the New Orleans authorities is a tremendous one, but so much the greater will be their triumph if they succeed in it and thereby prove to the world that it is possible to remove once for all from all civilized communicates the menace of the yellow peril.

## THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS venerable institution celebrated during the third week in July the quadricentennial of its incorporation, which took place actually on July 1, 1505. Its charter or "Seill of Cause" was granted by the town council of Edinburgh on petition of the "surregeanis and barbouris" that they be incorporated as one of the burgh crafts. This is, therefore, the oldest medical association in the United Kingdom, the Royal College of Physicians of London having been established thirteen years later. The College early gave itself to the teaching of anatomy, and this was followed by courses in surgery and other branches of the healing art. This was two hundred years before the Medical School of Edinburgh University was established as a direct offspring of the Royal College. The charter of the College provided for the examination of all practitioners and raised a barrier against quackery by establishing that "no maner of persoun occupie nor use any poyntis of oure saidis craftis of Surregerie or barbour craft within this burgh bott give be first frieman and burges of the samyn and that he be worthy and expert in all the poyntis belang and the saidis craftis deligentlie and avysitlie examinit and admittit be the maisteris of the said craft for the honorabill seruyng of oure Soveraine Lord his liegis and nychtbouris of this burgh. And als that everie man that is to be maid frieman and maister amagis was be examit and previt in their poyntis following. That is to say that he knaw anotomea nature and complexioun of every member in manis bodie. And in lykeways he knaw all the vaynis of the samyn that he may mak flewbothomea in dew tyme. And als that he knaw in quhilk member the signe hes domination for the tyme for every man aught to knaw the nature and substance of every thing that he wirkis or ellis he is negligent." The necessity of dissection as a means to the acquirement of a practical knowledge of anatomy was recognized in the grant of "ane condamnit man efter he be deid to mak anatomea of."

The surgeons and barbers gradually became separated in their practice, but they continued together in one guild until 1722, when the court granted the barbers leave to establish an independent corporation. In 1778 the College, until then a municipal corporation or guild, became, by charter from George III, "The Royal College of Surgeons of the City of Edinburgh." The College was still, however, under control of the city authorities and several acts of interference with the internal affairs of the institution by the town council are on record, one being an annulment of an election because the newly chosen president professed political beliefs obnoxious to a majority of the city fathers. In the early

part of the last century, this control of the civil authority over the College was severed, and the last indication of the municipal origin of the body was removed by a new royal charter granted in 1851.

The educational character of the College was prominent from its foundation, the teaching of anatomy being, as we have seen, one of the provisions of its charter. The petition for the grant of the dead body of a criminal for dissection was based upon the ground "quhairthrow we may haif experience, ilk ane to instruct uthers," and if the body were granted, the petitioners promised that "we sall do suffrage for the soule." In 1694 the town council granted further privileges for the study of anatomy on condition that the College should build an anatomical theater where they should once a year (a subject being obtainable) have a public dissection. In 1705 the College appointed one of its members teacher of anatomy, and the town council ratified the choice by conferring upon this teacher the title of professor of anatomy in the university. Some years later, Alexander Monroe, who was the anatomical teacher of the College, associated with himself four members of the College of Physicians, and those five were afterward made professors at the University, there establishing in 1725 the medical faculty of Edinburgh University. The diploma-granting power remained with the College, and as late as 1859 the single diploma of the College of Surgeons licensed the holder to practise not only surgery, but midwifery and internal medicine as well. At that time the single diploma was replaced by the two diplomas of the College of Physicians and of Surgeons. Finally, in 1884, another diploma was added and the license to practice in all branches was conferred by the combined diplomas of the College of Surgeons, the College of Physicians, and the Faculty of Physicians and Surgeons of Glasgow, this being known as the "triple qualification."

Many men, in America as well as elsewhere, owe much to this ancient institution, the oldest medical association in the English-speaking world, and the parent of the Edinburgh Medical School. The licentiates of the college have just cause to feel a pride in their connection with it, for honorable as has been its career in the past, it shows no signs of age, and is even now as active in furthering the good of the profession as at any time in its long career. All who have the cause of medical education and the advancement of the profession at heart will join the friends of the College in felicitations and in wishing it a long period of undiminished prosperity.

## ABUSE OF MEDICAL CHARITY.

This question is continually cropping up, and, in fact, has been so freely discussed that its reiteration has become, perhaps, somewhat wearisome. However, it is a matter of such consequence to the medical profession that its frequent and persistent agitation is justified and well advised. The abuse of medical charity is confined to no one country, but is more or less prevalent throughout the civilized world. In the cities of America the habit is especially conspicuous and is an evil which shows little sign of decrease.

Dr. George W. Gay, Senior Surgeon, Boston City Hospital, published in the *Boston Medical and Surgical Journal* for March 16, 1905, a paper entitled "Abuse of Medical Charity." In this paper the question of the abuse of medical charity is thoroughly reviewed, and the writer concludes that three sources of relief must be looked to, namely, the public, the trustees and managers of our medical charities, and the profession at large. Dr. Gay holds that the public must be educated to the facts of the situation, and taught that public hospitals are designed and supported for the poor and destitute and not for those who can afford to pay.

The trustees of medical charities should enforce the following two general rules: 1. All patients occupying private rooms in hospitals shall be required to pay the attending physician a fee for professional services, unless excused from so doing for good and sufficient reasons by the superintendent or other representative of the administration. 2. Out-patients shall be inspected and required to show in some way that they are worthy objects of charity. 3. Those patients who are able to pay something, even a small fee, shall be refused free treatment, under ordinary circumstances, but shall be directed and advised as to the best course to take to get relief.

Finally, Dr. Gay points out the obvious fact that the medical profession itself is to a great extent responsible for the present state of affairs. The fundamental rule for all physicians to observe is to encourage no patient who can pay a fee to apply at a free clinic. The writer holds, indeed, that judicious and persistent efforts on the part of the profession are absolutely essential to the success of the endeavor to do away with the abuse of medical charity.

## Pulmonary Tuberculosis in Penal Institutions.

At the approaching International Prison Congress to be held at Budapest, Hungary, September 3, 1905, one of the questions to be discussed is "What Are the Best Means of Combating and Treating Tuberculosis, and of Avoiding Its Propagation in Penal Establishments of Every Kind?" While it is the duty of those in authority to take measures for the limitations of this disease in institutions, it remains for the medical profession to indicate what these measures shall be. An investigation of the prisons of New York State and elsewhere shows that tuberculosis prevails to an alarming extent. Penal establishments call for especial care in this respect because a large number of those that compose their population bring with them either the germ of the disease itself or hereditary or acquired defects, which predispose them to this malady. The risk of infection is there combined with great receptivitiy. On their discharge, prisoners who have developed the disease during their detention, become agents for the spread of the contagion in the community. These dangers, which are sufficiently grave in penal establishments of all kinds, are a special cause of solicitude in colonies for juvenile offenders. It becomes the duty of society to secure the physical as well as the moral development of these unfortunate youths, and to omit no means of protecting them against contamination. It is desirable to indicate and to classify the measures of every kind already taken or projected to combat the propagation of tuberculosis in penal institutions. It would also be expedient to study how the requirements of science, of public health, and of humanity, may be reconciled with the necessity of penal administration. Among the measures to be discussed at the approaching Congress are the means of discovering sufficiently early and of classifying those who are sick or suspected

of being sick with the disease, general hygienic measures concerning persons and places, special measures as to preservation, isolation, or prophylaxis, and means of treating the sick individually. Dr. S. A. Knopf and the Rev. Samuel J. Barrows have been appointed by the Secretary of State delegates to the Congress for the United States Government.

### Ability of the Larvae and Pupae of the Stegomyia Fasciata to Withstand Desiccation.

Public Health Reports for June 16, 1905, contains a very interesting communication from Passed Assistant Surgeon T. D. Berry, of the Public Health and Marine Hospital Service, at the Port of New York, with regard to this matter. It is generally believed that mosquito larvæ and pupæ are unable to exist for more than a short time out of water. In Laredo, Texas, in the summer of 1904, observations to clear up this point were made. Dr. L. O. Howard mentions in his work on mosquitos that he has noted a small pool containing numerous larvæ which became entirely dry; yet the next day, after a rain, many larvæ were found swimming about in it. Other incidents of a like nature have been recorded. Dr. Howard's explanation of this incident was that the larvæ burrowed or sank in the soft mud, and thus lived from one shower to another.

Dr. Berry's observations did not bear out this theory. "The larvæ showed no disposition to burrow, but merely settled down on the surface of the mud as the water evaporated. And while it was shown that larvæ can stand drying for hours they could not have stood it for days and weeks; besides in Laredo the baked mud was ground into powder by the wheels of vehicles."

As *Stegomyia fasciata* was never found in puddles in Laredo, artificial experiments were necessary to determine its ability to withstand desiccation. Such experiments proved that the pupæ of this mosquito can be successfully hatched out of water, and that larvæ will live for a considerable time under these conditions.

Dr. Berry, therefore, is of the opinion that pupæ emptied on the ground on cloudy days or late in the afternoon, will probably hatch, and says that the mere emptying of a vessel containing stegomyia pupæ does not necessarily kill the pupæ.

### The Aërial Convection of Smallpox.

That the germs of smallpox may be borne by the air for some considerable distance is believed by many. In Great Britain, especially, this theory has gained ground during the past few years, and is upheld by the English Local Government Board. The belief has been more or less substantiated by the experience of London, Manchester, Glasgow, Liverpool, and Gateshead during recent outbreaks of smallpox. Dr. Claude B. Ker, Medical Superintendent of Edinburgh City Hospital, in a paper contributed to the *Edinburgh Medical Journal* for June, holds that belief in the theory of aërial convection of smallpox has been carried too far, and does not think that any absolutely conclusive evidence in its favor has been produced. He instances the situation of the Edinburgh smallpox hospital as showing that contiguity to such an institution does not necessarily mean a spread of the disease. The hospital in question is placed between the grounds of the permanent fever hospital and those of the poorhouse. Yet during the epidemic of smallpox which prevailed in Edinburgh in 1904, although within a quarter of a mile of the smallpox hospital, there is an average population of over 1,500, and within a mile one of probably 6,000 persons, no cases of the disease occurred which could in any way be attributed to hospital influence. Dr. Ker is inclined to agree with those who hold that defective administration on the part of the hospital authorities is responsible when there is an undue prevalence of smallpox in the immediate neighborhood of any such institution.

### The Work of the Netley School.

The military medical school connected with the Royal Victoria Hospital, Netley, Isle of Wight, has been closed, after a career of forty-two years, with a graduate roll of three thousand names. All the medical officers of the British Army since 1863 have studied at Netley, and for nine years the surgeons of the Navy were also educated there, until their own school at Haslar, was established in 1880. In a notice of the school in the *Journal of Tropical Medicine* it is said that the Netley School will be best remembered by the fact that it gave to the world a new science, Preventive Medicine. Until Parkes, the Professor of Preventive Medicine in the Netley School, published his great work, our knowledge of hygiene was merely empiric, but Parkes established a basis on which to found hygiene and preventive medicine as a science. Netley also originated another branch of medicine which has come markedly into prominence lately. Tropical medicine has formed a distinct part of the education of medical men joining the military services ever since the Netley School was founded, and this was the only school at which the subject was taught in Great Britain until a few years ago, when the London and Liverpool schools come into existence.

## News of the Week.

**The Fourth Centenary of the Royal College of Surgeons, Edinburgh,** was celebrated in that city on July 20 and 21. The opening exercise was a service in St. Giles' Cathedral in which, in Catholic times, was an altar to St. Mungo, the patron saint of the college. After the services, at which the Rev. Prof. W. P. Paterson preached a sermon on the philosophy of suffering, there was a luncheon in the city chambers given by the municipal corporation. The commemorative ceremony was held in McEwan Hall in the afternoon. The president of the college, Sir Patrick Heron-Watson, delivered an address, after which thirty-six honorary fellowships were conferred. The conferring of the honorary fellowship degree was a ceremony vested with the greatest interest. The honorary Fellows-elect were presented in turn by Sir Halliday Croom, the vice-president of the college, who submitted a short and eulogistic account of their medical careers, and they afterwards received the right hand of fellowship and their diploma from the president. Having been duly robed, they signed the roll of the college and took their seats on the platform to the accompaniment of a few bars of the national music of their respective countries. The following received honorary Fellowship: v. Elsberg and Fuchs of Vienna, Saxtorph of Copenhagen, Guyon, Championnière, Segond, and Terrier of Paris, Poncet of Lyons, v. Bergmann of Berlin, Bier of Bonn, Czerny of Heidelberg, König of Jena, Duranti of Rome, Saneyoshi of Tokio, Subbotin of St. Petersburg, Lennander of Upsala, Kroenlein of Zurich, Halstead and Howard Kelly of Baltimore, Keen of Philadelphia, McBurney of New York, Warren of Boston, Wm. J. Mayo of Rochester, Minn., Cameron of Toronto, Shepherd of Montreal, Fitzgerald of

Melbourne, McCormick of Sydney, Bomford of the Indian Medical Service, Herbert Mackay Ellis of the British Navy, A. H. Keogh of the British Army, Baron Lister, Arthur Chance, President of the Royal College of Surgeons of Ireland, John Tweedie, President of the Royal College of Surgeons, of England, Playfair, President of the Royal College of Physicians of Edinburgh, and H. E. Clark, President of the Faculty of Physicians and Surgeons of Glasgow. The name of v. Mikulicz-Radecki of Breslau was among those selected for the honor, and the diploma of honorary Fellowship, together with an expression of sympathy from the college was forwarded to his relatives. In acknowledging the honor bestowed, Dr. Howard Kelly thanked the oldest college for honoring the youngest of universities, and, perhaps more than all, he said, he had to thank them that they had welcomed back gynecology, an errant daughter, into the bosom of surgery. Dr. Keen said he was sure that were they to collect the suffrages of his colleagues that day they would all dispute the accuracy of the Virgilian maxim, for they would welcome, and not fear, the gift bearings of the Scots. He thought this was the oldest independent medical corporation in the world not connected with a university, and they might, therefore, well prize the honor conferred upon them that day. Though, through his father, he was a countryman of Professor Lennander (of Sweden), through his mother he was English, and through his grandmother, Welsh; he was now somewhat of a Scotsman, and if he went to Ireland, and obtained a little of the brogue he would be "totus teres atque rotundus." In the evening the president and fellows of the college held a reception in the Royal Scottish Museum.

**Yellow Fever in New Orleans.**—There are signs that the health officials in New Orleans are getting the yellow fever well in hand and the prospect of an early subsidence of the epidemic there is encouraging. It is now generally accepted that the fever got into New Orleans sometime between June 1 and June 15 through fruit vessels from Central America. The disease was not discovered until July 13, so that it had a month or six week' start of the health officers, and has been in the city nearly two months. This naturally has greatly increased the difficulty of arresting the progress of the disease since, when its presence was discovered, there were already many separate foci of infection. Only one of the seven municipal districts—the Italian quarter—is infected, and outside of it there have been but eight cases. These patients have all been screened from mosquitos and there is no danger of spread of infection from them. The outside quarantine situation has improved a little, Texas and Tennessee having modified somewhat the severity of their restrictions. The only panic-stricken region is Mississippi, whose Governor, Vardaman, is apparently the scaredest man in the two Americas: his terror has been increased by the occurrence of a case of yellow fever at Lumberton, in his own State. The Mississippi towns are even quarantining against each other in their fear. All passengers from New Orleans are transferred to new cars at the Mississippi line, which cars have been fumigated and disinfected. All of the windows have to be closed and nailed down while the train is passing through the State, and in many of the towns the trains are required to run through at a rate of not less than thirty miles an hour.

**The District Attorney and the Health Commissioner.**—District Attorney Jerome of this county has been enlivening the dulness of municipal midsummer politics by a criticism of the mayor and the "boss." He recently gave out an interview regarding the mediocre appointments of Mayor McClellan,and is reported to have paid his respects to the Health Commissioner in the following words: "Dr. Darlington is an agreeable gentleman, and may be a good physician. I like him personally, and he has made a fair Health Commissioner, but wouldn't his best friends laugh at any pretension that he was the equal of Lederle? Dr. Lederle was never a partisan. He was bred in the city service, and when the time came for a change he was made Commissioner. And there wasn't a physician in New York who wouldn't have told Mayor McClellan that he could not get a better man for the place. Yet Lederle was turned out. Why? He would have stayed only to serve the public. The man who turned Lederle out knew he was head and shoulders above Dr. Darlington in capacity, and yet he was put out. I am not specially attacking Dr. Darlington, but when we elect men to office we are entitled to the best service attainable." Mr. Jerome was not so happy in this case as when speaking of the Park Commissioner, Tenement-house Commissioner, and others. Dr. Darlington's appointment may have been unfit at the time it was made, but he has shown himself capable of learning, and has been a much better health officer than many of his predecessors.

**President Roosevelt's Visit to the Children's Hospital.**—On July 28, President and Mrs. Roosevelt, together with a party of guests, visited the Sea Breeze Hospital established at Coney Island by the New York Association for the Improvement of the Condition of the Poor. The hospital has accommodations for forty-five children with tuberculous bone diseases and the associated Sea Breeze Home can receive two hundred and eighty children and ninety mothers, who are each kept for a week's vacation. Among the members of the President's party were Dr. Herman M. Biggs, Dr. Charlton Wallace, Dr. Linsly Williams, Dr. William H. Allen, Dr. Walter B. James, and Health Commissioner Darlington. A report of the work of the hospital and the results obtained by this plan of treating tuberculous children at the seashore may be found in an article by Dr. Charlton Wallace, Attending Orthopedic Surgeon, appearing in the MEDICAL RECORD of July 22, 1905. The hospital, which is in need of funds, has recently received $25,000 from one donor and $5,000 from another.

**For a State School of Sanitation.**—The New Jersey State Board of Health has appointed a commission to consider the proposition of establishing a State School of Sanitation for the purpose of instructing local health officers in their duties, particularly during epidemics of infectious diseases. The method proposed is to hold conferences in the various cities of the State at which the instruction will be given, to be followed by practical demonstrations. The school in each city is to be made available to all applicants in that section, so that the whole State may be covered. The members of the commission are as follows: Dr. B. Van D. Hedges of Plainfield; Professor E. H. Loomis of Princeton University; Francis H. McGee, of Attorney-General McCarter's office; R. B. Fitz-Randolph, State Director of the Laboratory of Hygiene, and Dr. John L. Leal of Paterson.

**A Filtration Plant Needed for New York City.**—Health Commissioner Darlington in a report just sent to the mayor, urges the installation of a filtration plant for the purification of the city's water supply. The report contains a large amount of statistical matter showing the decrease in typhoid fever and intestinal diseases which has followed the introduction of filtration systems into the water sup-

plies of other cities. The efficiency of sand filter beds is discussed and their adoption is strongly recommended, as it is claimed that by this means it is possible to remove 99.5 per cent. of the bacteria in a water supply. Even the most extensive purchase by the city of the land surrounding the watershed would not furnish adequate protection against occasional contamination, and in times of drought the danger would always be much increased. It is estimated that a suitably covered slow sand filtration plant can be built for the entire Croton supply of about five hundred million gallons daily for about $17,000,000, with a total annual cost of operation, including interest, sinking fund, depreciation, etc., of about $900,000. The work could be completed within two years.

**New Hospital in St. Louis.**—Plans are being prepared for a new hospital to be added to the various Bethesda institutions in St. Louis. The institutions now operating under the Bethesda auspices are the Hospital and Home for Incurables, the Old Ladies' Home, the Home for Foundlings, and the Maternity Home. The new building will be devoted to the Maternity Home, the quarters now occupied by this branch being inadequate, and not up to the requirements for modern treatment.

**The American Association of Obstetricians and Gynecologists** will hold its eighteenth annual meeting at the Hotel Astor, New York, Tuesday, Wednesday, and Thursday, September 19, 20, and 21, 1905, under the presidency of Dr. Howard Williams Longyear of Detroit. Dr. Robert T. Morris, 616 Madison avenue, chairman, Dr. Samuel W. Bandler, 229 West 97th street, and Dr. James N. West, 71 West 49th street, constitute the local committee of arrangements, one or all of whom will furnish information to members and guests upon application. Dr. William Warren Potter of Buffalo is secretary of the association.

**Typhoid Fever in Chicago.**—The seasonal increase of typhoid fever in Chicago has set in more sharply than usual. There is a marked increase in the laboratory findings by the Widal test, and the hospital population shows a 35 per cent. increase of typhoid cases since the first of July. An analysis of the death-certificates, however, shows that in an increasing proportion of the fatal cases the disease was contracted outside of the city. For many years this proportion averaged 20 per cent. Since 1900 this proportion has steadily increased, until it is now shown that in fully 25 per cent. of all fatal cases of typhoid fever occurring in Chicago, the disease was contracted elsewhere.

**New Building for the St. Louis Medical Society.**—The St. Louis Medical Society recently voted to lease a plot of ground and erect a building in which to hold its meetings. The ground is the property of the St. Louis Medical Library Association, and the two buildings will join, being in reality one. Other medical societies of the city will be invited to hold their meetings in the new hall.

**State Prison for Inebriates.**—A petition has been presented to the Grand Jury in New Brunswick, N. J., praying that habitual drunkards be sent to State prison (instead of to the county jail) for a definite term. It is contended that they would then have a chance to reform and to learn a trade; but it is also admitted that at present their care is a considerable expense to the county.

**A Texas Fumigation.**—It is related in a New Orleans despatch to the *New York Times* that Dr. Tabor, Health Officer of Texas, has reported to the Marine Hospital service that a case of yellow fever had been found at Morgan City and that the people had burned the patient and the house and its contents. It is believed, or at least hoped, that the patient was dead when burned. These are strenuous quarantine methods even for Texas.

**Burning of an Ambulance.**—While an employee of the Health Department was disinfecting an ambulance used to take contagious patients to the hospitals on North Brother Island, at the department pier at 132d street and the East River, the gas from the mixture of alcohol and formaldehyde, which he was using, caught fire from the flame of his lantern, and exploded, setting fire to the ambulance and destroying it.

**The Reid Memorial Hospital,** Richmond, Indiana, a public institution, made possible by the gift of $75,000 by Daniel G. Reid of New York, was dedicated July 27. Wm. B. Leeds gave $10,000, and there were $35,000 in other gifts.

**Lamoille County (Vt.) Medical Society.**—At the third annual meeting of this society, held at Morrisville on July 12, the following officers were elected: *President,* Dr. C. C. Rublee of Morrisville; *Vice-President,* Dr. E. R. Brush of Cambridge; *Censors,* Dr. R. G. Prentiss of Johnson, Dr. G. B. Maurice of Waterville, Dr. F. S. Dillingham of Johnson; *Delegates* to the Vermont State Medical Society, Dr. George L. Bates of Morrisville, and Dr. S. G. Start of Cambridge.

**Doctors Fined for Contempt of Court.**—Two Washington, D. C., physicians have been fined $25 and costs each for tardiness in appearing at court in response to subpœnas. Both physicians were able to show that their delay was caused by professional work that could not be deferred, but the excuse was not accepted by the presiding justice.

**Southern Aroostook Medical Society.**—At a recent meeting of this society the following officers were elected: *President,* Dr. W. W. White of Bridgewater; *Vice-President,* Dr. H. L. Putnam of Houlton; *Secretary,* Dr. F. W. Mann of Houlton.

**Ambulance in Collision.**—A St. Vincent's Hospital ambulance last week collided with an ice wagon at Houston and Thompson streets. Both the surgeon, Dr. Burk, and the driver were thrown from their seats and bruised, while the ambulance was badly smashed.

**Resignation of Professor Simpson of Edinburgh.**—Professor Alexander Russell Simpson, who for thirty-five years has filled the chair of midwifery in the University of Edinburgh, has handed in his resignation to take effect from August 31. Professor Simpson succeeded his uncle, Sir James Y. Simpson in the occupancy of the chair.

**The United States Pharmacopeia.**—The eighth revision of the U. S. Pharmacopœia has just been issued, and its provisions will officially go into effect September 1, 1905. Among the changes made those of especial importance are in the strength of the tinctures of aconite, veratrum, and strophanthus. The strength of tincture of aconite has been reduced from 35 per cent. to 10 per cent., and that of tincture of veratrum from 40 per cent. to 10 per cent. The strength of tincture of strophanthus has been increased from 5 per cent. to 10 per cent. These changes have been made in order to conform to the standards adopted by the International Conference on Potent Remedies held at Brussels in September, 1902, the object being to make uniform the strength of potent remedies in all parts of the world.

**The International Congress on Tuberculosis** will be held in Paris, October 2-7, 1905. The work of the Congress will be divided among four sections as follows: Medical Pathology, chairman, Prof.

Bouchard; Surgical Pathology, chairman, Prof. Lannelongue; Prophylaxis and Treatment in Infants, chairman, Prof. Grancher; Prophylaxis and Treatment in Adults, and Social Hygiene, chairmen, Prof. L. Landouzy and M. Paul Strauss. The official languages of the Congress will be French, German, and English. The fee for an active member of the Congress is 25 francs, that for an associate member (wife or member of the family of an active member) is 10 francs. The treasurer, to whom the amount of the fee is to be sent, is M. Pierre Masson, 120 Boulevard Saint-Germain, Paris.

**The Late Dr. Schiff.**—At a meeting of the Medical Board of the St. Mark's Hospital of the City of New York, held July 27, the following resolutions were adopted: *Whereas,* Our friend and beloved colleague, Dr. Herman J. Schiff, who was so highly esteemed by all who knew him, as to his professional ability, reputation, and honesty, has been suddenly called away to his eternal rest; and *Whereas,* the hospital lost a member and sincere friend, who always fulfilled his duties, and whose family loses a loving father and husband; *Resolved,* That we all regret the sudden loss of our late colleague, that we all mourn our loss, and that we extend to the family our heartfelt sympathy and sincere regret in this sad hour of affliction; and it is further *Resolved,* That a copy of these resolutions be spread on the minutes of our Board, and a copy be sent to the bereaved family of our deceased colleague, and that they be published in the medical press. Signed: Dr. Carl Beck, President of the Hospital; Dr. Reynold W. Wilcox, President of the Medical Board; Dr. Ignatz Morvay-Rottenberg, Secretary of the Medical Board.

**Obituary Notes.**—Medical Director Samuel Jackson, retired, U. S. N., died at his home in Washington, D. C., on July 22. Dr. Jackson was born April 1, 1817, in Pennsylvania, and was appointed assistant surgeon for North Carolina in 1838. He was promoted to medical director in March, 1871.

Dr. O. B. Hicklin died at his home in New London, Mo., on June 28. He was born near Madisonville, Mo., September 24, 1833, and was educated in the common schools of his native State. He was graduated in medicine from the College of Physicians and Surgeons of Keokuk, Iowa, in 1876, and practiced in Missouri during his entire professional life. During the Civil War he served in the Confederate army under General Price.

Dr. Jacob Ebersole of Cincinnati died at his home July 27, at the age of eighty-six. He was born in 1820, at Eaton, Ohio, graduated at the University of New York, and then practised for twenty years at Aurora, Ind. He served as a surgeon in the Civil War.

Dr. J. H. Stringfellow of St. Joseph, Mo., died in that city on July 24, aged 86. Until a few years ago, when he retired from practice, he was one of the leading physicians of Western Missouri. He was graduated in 1845 from the Medical Department of the University of Pennsylvania. It is said he was the founder of the town of Atchison, Kansas, in 1854. He was a prominent figure in the troublesome times incident to the settlement of Northeastern Kansas and Northwestern Missouri.

Dr. D. C. Dunn of O'Fallon, Ill., has died suddenly of apoplexy. He was in his sixty-second year and was a prominent physician in O'Fallon. He was a member of the board of education and a justice of the peace. He was a graduate in medicine of the Louisville Medical College in 1872.

Dr. John F. Graves of Montgomery City, Mo., committed suicide on July 4 by shooting himself through the heart. He had been suffering from an attack of grip for some time, and despondency is supposed to have been the cause for the act. Dr. Graves was local surgeon of the Wabash Railway at Montgomery City, and had been a prominent citizen for a quarter of a century. He was a member of the Montgomery County Medical Society, and of the Missouri State Medical Association. He was fifty-eight years of age. He was graduated in medicine from the Medical Department of Washington University in 1878.

Dr. William K. Carroll of Queenstown, Md., died in Arrow, Colo., on July 18, at the age of fifty-six years. He was a graduate of the University of Maryland School of Medicine in the class of 1873.

Dr. Uriah Long of Schuyler, Neb., died July 16, at the age of seventy-three years. He was a graduate of the Bellevue Hospital Medical College in 1865.

Dr. James Hedenberg of Medford, Mass., died July 26. He was born in Troy, N. Y., in 1831, and was graduated from the Castleton, Vt., Medical School in the class of 1852. He had resided in Medford since 1854. He was for some years a practitioner of the homeopathic school, a professor of the diseases of children in the Boston University Medical School, and for one year president of the Massachusetts Homeopathic Medical Society. Later he returned to regular practice and became a member of the Massachusetts Medical Society.

Dr. Thomas G. Horn of Colorado Springs, died July 14. He was a graduate of the St. Louis Medical College in 1868.

### OUR LONDON LETTER.

(From Our Special Correspondent.)

COMING VACATION—PRIZES—MALIGNANT EMBRYOMATA—ECTOPIC GESTATION SAC—ADHESIONS AFTER ABDOMINAL SECTIONS—R. C. S.—SHEFFIELD UNIVERSITY—ITEMS—OBITUARY.

London, July 14, 1905.

Signs of the coming vacation are upon us. Distributions of prizes at the medical schools and anticipations of the closing of the session inspire the talk of both teachers and students. Then the program of the British medical interests those who mean to attend the annual meeting, whether for the picnic or the more serious side. Leicester, the meeting place this year, can scarcely compare with Oxford, which attracted so many last year, but is full of other kinds of interest, and from all one can gather at present the prospects of a successful meeting are very good. It is quite certain that the hospitalities shown will be on a scale to be remembered, and the provision for the amusements of members seems to grow from year to year. In fact, not a few grumble that the picnic side of the meeting should so overshadow the scientific. Those who have papers in hand join in deprecating the attractions which draw so many away from the Sections, but the majority really attend for a week's enjoyment as the commencement of their annual holiday.

Turning to the schools—Lord Ludlow distributed the prizes at Barts' on Wednesday, and gave some interesting facts as to the progress of school and hospital. Two additional operating theaters, he said, had been completed, and it was hoped to start the pathological block very soon. In that connection, old Bart's men had subscribed no less than £1,547 toward the block, and £8,047 to the general fund. The late Mr. Luther Holden bequeathed £3,000, to endow a surgical scholarship in the school where he taught for so many years. Towards the new out-patients' department £108,000 has been promised. The contract price was £125,000, and, Lord Ludlow declared, though he was averse to taking risks, he felt he could guarantee the remainder would be subscribed before the work was finished. He was a County Councillor, and hoped the Council would never have charge of our hospitals. He concluded by asserting theirs was "the best school in London, and had the best doctors and surgeons" attached to it.

A similar claim, though in rather less boastful terms, was put forth on the same afternoon for Guy's, when, besides the distribution of prizes, the opening of the Gordon Anatomical and Pathological Museum, and a garden party,

drew more than one thousand ladies and gentlemen to the celebration. The Dean stated that the school had always paid its way, without any subsidy from the hospital, but on this, as on many previous occasions, it was compelled to appeal to the liberality of the wealthy, while claiming that it now possessed the most ample and efficient laboratory and teaching accommodation in London.

Dr. Pye Smith distributed the prizes, and presented to Mr. Robert Gordon, on behalf of the governors and medical staff a miniature copy in silver of the statue of Thomas Guy, which stands in front of the hospital, and with it a book of signatures, including that of the Prince of Wales, president of the hospital.

Mr. Gordon is a governor of the hospital, and has presented the museum to the hospital. It will accommodate the 12,000 specimens of the old museum in a manner allowing them to be properly displayed.

At the Obstetrical Society, on the 5th inst., Mr. J. H. Targett and Mr. H. T. Hicks related two cases of malignant embryoma of the ovary, and remarked that such cases were commonly grouped among teratomata. They preferred the name given, and concluded that these embryomata are rare; that they usually occur in young adults, but have been met with in childhood; that secondary growths are usually restricted to infection of the peritoneum, and may present the same structure as the primary tumor, or be composed entirely of sarcomatous elements; that pain and ascites are constant symptoms; that the ascites may precede prenitoneal infection, and in some cases a diagnosis of twisted ovarian cyst has been made; ovarian tumors, having an irregular disposition of embryonic elements are very liable to be malignant.

Dr. Boxall showed an extrauterine gestation sac, which had ruptured in the fifth month, on which Dr. Herman remarked that after mid-term rupture became rarer as the months went on. In the first half of ectopic pregnancy rupture was frequent and the risk of operation slight; in the second half rupture was rare and the risk great.

Dr. H. J. Paterson showed a loop of small intestine adherent to the stump of an ovarian tumor, and thought it emphasized the importance of leaving the pedicle free from knots, and also of obtaining early intestinal movements.

Dr. Herman asked if any one had ever opened the abdomen within a few weeks of its section and found no adhesions. He had never seen such a case, nor even heard of one. Adhesions were the certain result of abdominal section, and were absorbed in the course of time.

Dr. Macnaughton Jones thought it was a mistake to be too anxious about the bowels. He preferred a saline to calomel, when something was required.

Yesterday afternoon, Mr. John Tweedy was reelected President of the Royal College of surgeons. Mr. H. T. Butlin and Mr. Edmund Owen were elected Vice-Presidents.

On Wednesday, the King opened the buildings of the new Sheffield University, amid great rejoicings of the citizens and expressions of loyalty.

King's College announces vacation courses of bacteriology and pathology, specially suited to the requirements of medical men, to begin on July 26, and close on August 5.

The Metropolitan Hospital has attained its sixty-ninth year, and at the dinner on Tuesday it was stated that the annual expenditure averages £13,000, but the subscriptions only amount to £1,096. The chairman, Lord Howard de Walden pleaded for "several absolutely ablebodied philanthropists" to come to the rescue. The list of donations announced amounted to £3,825.

At the twelfth annual meeting of the National Society for Employment of Epileptics the general health of the patients was reported to be very good. A new home for the special benefit of Hampshire cases has been opened, as well as an administrative house and various other buildings. The accommodations, however, is still entirely insufficient.

A meeting of the Hospital Sunday Fund was held yesterday. The church collections so far show an increase over those of last year, when the total sum received was £63,000. The collections this year will exceed £75,000, including the bequest of £12,500 already referred to, and it will be the largest collection ever made since the foundation of the fund, in 1872. Mr. George Herring's contribution to the fund last year amounted to £11,926.

The other half of the £25,000 previously reported as bequeathed by Mr. Cook has been assigned to King Edward's Fund, which is also to benefit by the residue of the estate of the late Mrs. F. M. Hames, which is likely to exceed £50,000, left on trust to the fund, subject to her husband's life interest.

Dr. Alfred B. Barton died on the 5th inst., in his eightieth year. After an adventurous life, he retained excellent health up to within a few days of his death. He saw the yellow fever epidemic in the West Indies in 1848. He was in the Crimea in 1855, in China in the war of 1860. The next year he explored the Yangtse-Kiang with two friends, and all three received the gold medal of the Geographical Society.

Other recent deaths were: Fleet-Surgeon R. W. Anderson, who died on the 5th inst., aged forty-nine, and Edmund Metcalfe, F.R.C.S., on the 3d, aged eighty-six.

## OUR VIENNA LETTER.

(From Our Special Correspondent.)

THE ACTION OF CHOLIN ON LYMPHATIC TISSUE—THE BIOLOGICAL EFFECTS OF RADIATIONS—GASTRIC AND INTESTINAL ULCERATIONS FOLLOWING LAPAROTOMIES—A PECULIAR TYPE OF LEUCOCYTOSIS.

VIENNA, July 10, 1905.

DRS. EXNER AND SYWEK have described the results of animal experiments made with cholin. Several months ago observations were carried out showing that on the injection of cholin into the skin and testicle changes were produced similar to those resulting in these situations after subjection to the action of the Röntgen ray or radium. In the present series of experiments cholin was injected into the peritoneal cavity, or between the layers of the mesentery, in cats and rabbits. It was found that characteristic lesions were produced in the lymph nodes and in the spleen. On comparing a normal mesenteric gland with that of a rabbit that a month previously has received an intraperitoneal injection of cholin it is found that there has been a great diminution in the amount of lymphatic tissue, and the same thing is observed in the spleen. To summarize the results of these experiments, it may be said that intraabdominal cholin injections produce a macroscopical decrease in size of the lymph nodes and of the spleen, which is dependent on a destruction of the microscopic structural elements of these tissues. These appearances are very similar to those following the application of the Röntgen rays, and suggest the possibility of treating diseased lymph glands in this way.

At a meeting of the Society of Internal Medicine, Dr. Schlachta presented a paper on the theory of the biological effect of radiations. Werner has shown that on injecting into animals lecithin that has been subjected to the radium rays, necrosis similar to that produced by radium results. He concluded that the lecithin was broken up in the skin into toxic substances, and that this property of the lecithin was increased by the action of the radium. Cholin, a decomposition product of lecithin, gives rise to the same ulcerations, and Schlachta was able by ozonizing lecithin to produce loss of hair and ulceration on injecting it into the skin. He concludes that the lecithin of the tissues under the action of the Röntgen rays or radium rays becomes oxidized and more unstable, the necessary oxygen being found in the tissues, the decomposition products then giving rise to ulceration and loss of hair. The action of the rays, therefore, seems to depend on the presence of oxygen. The experiments with cholin showed that the intracutaneous injection of mineral doses of alkalis, and also of acids, can give rise to loss of hair and ulceration, so that the action of the radiations may also depend on a caustic effect. It might therefore be advisable to use small quantities of caustics in conjunction with the Röntgen or radium treatment. Dr. Freund said that he had obtained ulcerations of this sort by the injection of lecithin that had been subjected to the action of blue light.

Professor v. Franqué of Prague addressed the Society of Obstetricians and Gynecologists on the fatal affections of the gastric and intestinal mucosa following laparotomies. He first discussed the formation of discrete ulcerations of the gastric mucosa, especially about the lesser curvature, illustrating his remarks by reference to two cases of his own that ended fatally, and by numerous citations from literature. He ascribed these lesions to a retrograde embolism of the mesenteric vessels, and said that the melena of the newborn could be explained in the same way. After ligation of the cord, thrombi frequently form in the umbilical vein, and these are carried back into the portal vein. Friedrich artificially produced such ulcerations in guinea pigs, though they did not occur about the lesser curvature. Gussenbaur observed them after operations on incarcerated hernias, and as he believed they were caused by distention of the gut, called them distention ulcers. Others accuse the anesthesia, which is said to give rise to circumscribed brain lesions, and still others suppose that the Trendelenburg position may induce them by the compression of the portal vein. V. Breuscher observed gastric hemorrhage as a sequel to a traumatism of the brain. Franqué said he had lost one case through perforation of the intestinal ulcers after a gynecological operation, and the autopsy pointed to poisoning with bichloride of mercury. He therefore cautions against the double use of this antiseptic in both the vagina and on

the skin, as dangerous absorption can take place through the epidermis, which is often injured by the other steps of the sterilization. In the discussion following this communication, Haberer expressed himself as believing that the elevated pelvic position, which is used by surgeons oftener than by gynecologists, might give rise to gastric bleeding. Subcutaneous infusions of salt solution, given up to five to six liters a day, form an important part of the postoperative treatment, and ice should be applied externally over the stomach. Schauta, in this connection, described several cases of hemorrhage and gastrointestinal ulcers after gynecological operations. One of these was a complete hysterectomy for fibroids followed by fatal sepsis.

At the autopsy the mucosa of the stomach was found studded with small erosions, and there were intestinal hemorrhages. One month after another hysterectomy there was repeated vomiting leading to marasmus and death, and the autopsy revealed a good-sized duodenal ulcer and blood in the intestine. After a salpingectomy for ectopic gestation, followed by vomiting and intestinal obstruction, a second laparotomy was done, and the transverse colon was found occluded. At the autopsy there was found general anemia, peritonitis, and perforation of small gastric ulcers. In another case a complete hysterectomy for carcinoma was followed by hematemesis, progressive asthenia, and death; numerous crosions were present throughout the stomach. He said that several theories deserved consideration in these cases, but that the action of bichloride of mercury could hardly be involved, as otherwise the condition would be seen so much oftener.

Dr. Türk reported to the Society for Internal Medicine three cases of leucocytosis in which peculiar polymorphonuclear neutrophilic cells were found. About a year ago Arneth published a work in which he announced a revolution in hematology, but his efforts received but little notice. He called attention, however, among other things, to a certain type of cells which are said to be characteristic of severe general septic infections, and which coincide with the observations of Türk. The first case mentioned by Türk was a typical cholecystitis with chills, cyanosis, collapse, and pain. The leucocytes numbered only 10,200, with 80 per cent. of neutrophiles. Among these was a considerable proportion remarkable for unusual size, paleness, and plumpness of the nuclei. The nuclei were simple, not broken up into several parts, but lobed. The case was operated on, but died in two days. The second case was an appendicitis with typical sacculated exudate, distention of the abdomen and rapid pulse, and looked like a desperate case. The blood examination showed 28,000 white blood cells, but there were only 2.7 per cent. of cells with lobed nuclei, as against 23 per cent. in the other case. The patient was operated on and recovered. The third case was one of appendicitis with severe pains, distention of the stomach, and tachycardia. Examination of the blood showed 42 per cent. of typical polymorphonuclears and 44.1 per cent. of cells with lobed nuclei. On operation a perforation of the appendix was found, and a diffuse purulent peritonitis. The patient died. Examination of the blood of a moribund patient one hour before death revealed a low leucocyte count with 40 per cent. of lobed cells and 40 per cent. of ordinary leucocytes. These observations make it seem likely that severe septic conditions are associated with a large number of these abnormal, large, poorly granulated, plump, chromatin-poor cells.

## OUR BERLIN LETTER.

(From Our Special Correspondent.)

BERLIN, June 29, 1905.

EPIDEMIC CEREBROSPINAL MENINGITIS—MUCOUS COLITIS.

BERLIN medical circles have recently been much interested in the subject of epidemic meningitis. Three authorities, Kirchner, Westenhoeffer (both of whom were sent by the government to Silesia), and Grawitz, have spoken before the Medical Society on this subject, in which they have all had considerable experience. I have already discussed Kirchner's paper, which was read also before the Prussian Parliament. Westenhoeffer discussed this disease in relation to its pathological anatomy and its manner of infection. He has performed twenty-nine autopsies, and in every case has found an edematous swelling of the tonsils, which also involved the posterior wall of the pharynx. The Eustachian tubes were also red and swollen. The nose was affected in only three cases, but there was middle ear inflammation in 70 per cent. of the cases. This authority believes that the disease always starts in the lymphatic tissue of the pharynx, from which it extends to the meninges, involving a region behind the chiasm over the sella turcica. The infection travels through the sphenoidal bone, or perhaps along the carotid. As to the involvment of the internal organs, the speaker noted swelling of the spleen, nephritis, swelling of the glands of the neck, enteritis, and swelling of the thymus gland. Bacteriological researches showed several cocci. On account of the predisposition of the tonsillar tissue to be affected by this disease is explained the fact that scrofulous children are especially susceptible to this disease. Thorough disinfection of the nose is the best prophylactic remedy.

Grawitz, in his paper, said that he had not noticed any alterations in the pharynx in his cases. In the cerebrospinal liquid he found chiefly the diplococcus of Fraenkel-Weichselbaum. The differential diagnosis between epidemic and tuberculous meningitis is very difficult. However, in general, the mononuclear lymphocytes are the most frequent cells found in the cerebrospinal liquid in the cases of tubercular meningitis. In epidemic meningitis, more polymorphonuclear leucocytes are found. In the line of treatment he recommended lumbar puncture and frequent rectal injections of salt solution. In the discussion following these papers, Heubner disagreed with the theory that the lymphatic constitution predisposed the child to this disease. According to him, a frequent symptom of epidemic meningitis is marked anorexia. Senator recommended hot baths, and if these were impossible, he advocated the use of hot air. Michaelis has always found in cases of tuberculous meningitis Koch's bacilli in the cerebrospinal liquid. V. Hausemann has not always had the same experience. In one of his cases the pharynx had undergone no changes whatever.

A question which up to the present time has always been in dispute is that concerning the nature of mucous colitis. Elsner spoke in the "Verein für innere Medicin" on May 29 on this subject. These cases have been studied at autopsy. There are two types; the catarrhal form may occur in every case of obstipation. The speaker found that chronic obstipation caused this trouble in thirty-eight cases out of sixty which he had studied. The second type is the nervous form. This may be either acute or chronic, but the disease is not common The speaker had seen eight cases which displayed almost invariably other signs of neurasthenia. As mixed types are very common, the differential diagnosis cannot be made in all cases.

## Progress of Medical Science.

*New York Medical Journal, July 29, 1905.*

**Cyst and Hydrocele of the Canal of Nuck.**—A case of this rare condition is reported by B. S. Talmey, whose patient was an unmarried woman of 32 years. Nine years before coming under observation, a growth the size of an egg appeared in the right inguinal region. A truss was applied, worn one year, and then discarded, as the mass disappeared in the course of a year. Two and a half years ago a smaller mass appeared a little lower than the one previously found. Under various applications this mass, considered a bubo, also disappeared. It reappeared, however, three weeks before the case was first seen by the author, who made the diagnosis stated in the title. This was confirmed by operation, as the opening of the inguinal canal revealed a cyst the size of a hazel nut within the substance of the round ligament, surrounded by perficystical fluid. The pericystical lumen was in connection with a narrow canal leading into the pelvis. This lumen contained about two tablespoonfuls of a serous fluid. The capsule of the cyst was transparent. Upon the removal of the cyst and the introduction of a finger into the vagina to lift the uterus, several drops of fluid could be seen to empty from the opening of the canal. This plainly showed that the intrapelvic part of the round ligament also contained some fluid. The round ligament was then extirpated as far as the external inguinal ring, and the ligament sewed on as in the typical Alexander's operation. The recovery was uneventful.

**The Simulation of Appendicitis by Cholelithiasis.**—A case of this nature is reported by G. C. Lempe, his patient being a man of 47 years. The author notes that a point of differential diagnosis in doubtful cases is the absence of indican in uncomplicated cholelithiasis. Albumin is frequently found during and after biliary colic, but its presence is not a constant diagnostic symptom. A leucocytosis may confirm the diagnosis of appendicitis, yet, on the other hand, a high leucocyte count may result from incipient gangrenous processes found at the fundus of the gall-bladder in advanced cases of biliary calculi. Icterus may or may not be present, according to the location of the stone. The two diseases may occur together, when the infecting germ responsible for cholecystitis is derived from the appendix. Becker has collected thirty-four such cases. The author closes with quoting the classical statement of Nothnagel to the effect that an abnormally situated appendix, an elongated gall-bladder, an inflammatory or edematous thickening of the gall-bladder, and inflamed peritoneal cov-

ering of the liver and colon, serofibrinous masses enclosed by inflamed peritoneum or fecal matter in the hepatic flexure might so change the outline and area of pain that it might be difficult to differentiate disease of the appendix, gall-bladder, or colon.

**Pruritus Ani, with Special Reference to Its Local Treatment.**—In addition to the removal of any obviously exciting cause, L. H. Adler, Jr., advises the daily injection into the rectum of from 4 to 10 c.c. of the following mixture: fluid extract of hamamelis, 1 dram; fluid extracts of ergot and hydrastic and compound tincture of benzoin, of each, 2 drams. If the perianal skin is rough and dry, it should be generously painted with a silver nitrate solution, 960 grains to the ounce. This should not be repeated oftener than every fourth day. On the day succeeding this application the skin should be coated with citrine ointment. A T-bandage should cover the entire region. Intense pruritus may be relieved by bathing the anal region with water as hot as can be borne, but no rubbing should be permitted. This last precaution is especially important, as contact with the hot water momentarily increases the itching. Following the water, either the lotio ingra or calomel ointment should be applied. For the first two or three weeks the patient should be seen daily, then on alternate days for a like period, and finally, once or twice a week. Six months are usually required for a complete cure, but no definite promise can be given as to the time required.

*Medical News, July 29, 1905.*

**The Bacterial Content of the Railway Coach.**—J. J. Kinyoun contributes an interesting article on car sanitation. His examinations included dust from carpets, interior furnishings, car air, and contents of drinking cups. He also describes and illustrates methods of car cleaning, and adds observations on the health of employees. The experiments revealed the presence of (among other organisms) the pneumococcus, staphylococcus pyogenes aurcus, streptococcus pyogenes, tubercle bacillus (only once positive and once doubtful), diphtheria, septicemia, and malignant edema. Of 196 animals inoculated with dust suspensions from the carpets, surfaces of the car, and car air, 73 per cent. proved negative. This, however, as the author states, applies only to animals; with human beings the results might have been different. The experiments were made on cars of trunk lines centering in Washington, D. C. He finds that the air-blast is the preferable method of cleaning a car. He did not find any facts leading to the belief that car employees, including carpet cleaners, were engaged in an especially hazardous occupation. He finds that among parlor-car porters there is a growing fear of contracting tuberculosis, and that they are particularly careful in keeping their cars clean, especially if tuberculous patients are among the passengers.

**The Cure of Leprosy.**—Isadore Dyer gives a brief description of the clinical features of leprosy, and appends the histories of ten personal cases. He makes the following points on the basis of his own experience: (1) Full diet, restricting only indigestible foods is indicated. The disease seems in nowise to be affected by fish or any other particular article of diet. (2) Baths are essential in the treatment. Hot baths twice a day, with or without soda, are effective. (3) The patient needs tonics, febrifuges, and should be watched for intercurrent or complicating diseases, such as malarial infection, pleurisy, pneumonia, grippe, and the like. (4) Strychnine is a *sine qua non* in the treatment of leprosy. (5) When chaulmoogra oil is given it is better endured before meals that after. It is best taken in capsules, in hot milk, or in milk of magnesia. The dosage should be begun small, say 3 drops, and increased every second or third day until as much as 120 to 150 drops of the oil are taken at the dose. At times it is advisable to give the oil in pill form. This can be done either combining it with extract nux vomica and ordinary excipients or a very effective way is with tragacanth and common soap. (6) Above all things, individualize the patient. Watch for improvement, and if it does not show in three months, wait six months—if it does not show in six months, wait a year, or longer. But keep on driving at the treatment until the patient dies or gets well. (7) When all evidences of the disease are gone, insist on a continuance of treatment. It may not be necessary, but it makes sure.

**A Comparison of Methods of Lavage with the Siphon Tube and Politzer Bulb.**—P. J. Sawyer prefers the use of the Politzer bulb. He uses the simplest form of the latter, with a glass connection for the tube. The patient takes the reclining position, with clothes loosened. The food residue in the stomach having been asperated as completely as possible with an empty bulb, a bulbful of solution, medicated as desired, is slowly introduced into the stomach, and free, active manipulation of the overlying abdominal wall is made, sometimes also shaking of the posterior surface of the stomach in cases of atony and dilatation without ptosis. A considerable movement of the fluid within the viscus is thus produced, thereby cleansing it and bringing the medicated solution in thorough contact with the surface. Then the operator allows the contents to be withdrawn in the aspirator which, till this time, has been controlled by pressure with the hand, and theauthor finds that in this way he can cleanse the organ more thoroughly and with less fatigue to the patient than he can by using the siphon tube.

**Pathological Changes and the Spirochæta Pallida in Congenital Syphilis.**—Babes and Panea describe the results of very careful and complete pathological examinations made in the bodies of three syphilitic infants dying very shortly after birth. Nearly all the organs were found affected by the disease, and the blood exhibited changes of a peculiar leukemic type. Spirochetæ were found in the organs of all three cases, particularly in the third, which was more thoroughly studied than the others. In this the organism was demonstrated in the following situations: The conjunctival secretion, pemphigus vesicles, the pharyngeal secretion, the meninges, pulmonary juice, heart blood, bone marrow, spleen, liver, kidney, thymus, lymph glands, and adrenals, the largest numbers occuring in the liver, adrenals, and lymph nodes. The spirochetæ were found unmixed with other microorganisms in the interior of these organs, whereas the surface of the body was free from them, and no other germs could be identified anywhere throughout the cadovers. No spinochetæ were found in the organs of infants not affected with syphilis. The authors conclude by saying that they believe that they have furnished additional evidence suggesting the relationship between the spirochæta pallida and syphilis.

**Observations on Malignant Tumors of Mice.**—Erlich and Apolant publish some of the results obtained in the course of their work on the malignant tumors of mice carried on during the past two and a half years. The material comprises 164 primary tumors, which are either pure adenomata or adenocarcinomata of alveolar or papillary type. It appears that the mamma invariably forms the starting point of these growths, which were always obtained from old females. During the period of observation, seventy-one of the tumors were inoculated into other individuals, but only ten continued to grow after transplantation. Age and sex of the inoculated mice seem to make little difference. In several cases the transplantations were continued for forty or more generations, in one case sixty having been secured. In order to show the proliferative energy of these growths, the authors say that it is easy to secure from each tumor by inoculations ten others which in a week reach the weight of 1 gram. If the process were carried out for sixty generations, which would take a little over a year, the resulting total tumor mass would form a sphere whose diameter would exceed that of the sum 890 millions of times. An interesting observation was made in one case in which up to the ninth generation the tumor continued as a carcinoma, but then began to develop as a mixed tumor, and by the fourteenth generation had lost all trace of its carcinomatous origin, and had become a pure sarcoma.

*American Medicine, July 29, 1905.*

**Epigastric Linea-alba Hernia as a Little Recognized Source of Abdominal Pain and of Gastric Symptoms.**—D. D. Stewart says the occurrence of hernia in the linea alba above the umbilicus, hernia most frequently of small size and often only apparent on minute examination, and its importance as a source of gastric symptoms, has received far too little attention by both clinician and surgeon. These hernias are small, sometimes barely perceptible to the eye, and in other instances fairly evident on inspection. Symptoms are usually referred to the stomach, whence a diagnosis of some form of gastric disorder, gastritis, gastralgia, and even gastric carcinoma or gallstone may be made by the unwary. The apparent triviality of the protrusion, even if it does not escape recognition, often does not suggest itself to the physician as a likely source of the malady.

**Phthiriasis.**—John Knott (Dublin, Ireland) has made the occurrence of some striking cases of phthiriasis in his practice the nucleus of an extremely interesting and exhaustive account of the various aspects of this condition. The lousy disease (morbus pediculosus vel pedicularis) has figured more largely than probably most readers had been aware, not only in clinical history, dermatology and pathology, but in general phrase and fable, in political history, in imperial and ecclesiastical biography, in orthodox theology, and in the endless mazes of heathen mythology. Dr. Knott's paper contains the principal available items from all these sources of information and imagination, and offers most interesing as well as instructive reading. Some of the pedicular lore is certainly very fantastic, and throws a strange light on some of the byways of human thought. In his concluding sentence he offers "the opinion that the scientists who succeeds in plucking out the heart

of the mystery of the triplex 'natural selection' topographically displayed in the life history of human pediculi will have done more toward establishing a true theory of parasitic and infectious disease than has hitherto been reached by bacteriological pathology." This statement of opinion implies that the writer is not satisfied with the "germ theory" as understood at present.

**Meningitis.**—S. MacCuen Smith gives a thorough review of the symptomatology, diagnosis, and treatment of this disease. He says meningitis manifests itself in a protean manner. Occasionally the symptoms are so typical that it is impossible to mistake the affection, and at other times they develop in such a latent form that only with the greatest difficulty and by the most careful attention to the etiology can a tentative diagnosis be made. At to the treatment, apart from employing general methods, such as the use of rest and the application of cold, very little can be accomplished. Surgical interference is naturally indicated in most cases of meningitis complicating aural disease. This procedure, however, is satisfactory only in a very small percentage of cases, chiefly from the fact that the serious nature of the ear disease is not recognized until the meningeal inflammation has become well established. Lumbar puncture is employed largely for the purpose of relieving pressure, and in some cases of noninfective meningitis, uremia, etc., actually startling results have been reported. However, Dr. Smith's experience has led him to believe that lumbar puncture is of value chiefly as a means of diagnosis. The cerebrospinal fluid has a normal specific gravity of about 1.010, and contains little or no albumin. In meningitis the albumin is greatly increased, while in cerebral abscess it is only slightly increased. It is claimed that the presence of more than 1 per cent. is pathognomonic of meningitis. Dr. Smith reports a case of meningitis complicating aural disease.

**Regional Analgesia in the Surgical Treatment of Anorectal Diseases.**—J. Rawson Pennington says that after some dissections and experimental work he found that it is possible to surround the nerves supplying the anorectal region quite successfully with an analgesic solution injected sypodermically, and he shows by illustrations how the various nerves to this region may be thus blocked off. To secure perfect analgesia of the anus and lower rectum would necessitate the complete blocking of all of these nerves. However, blocking of the inferior hemorrhoidal, the perineal branches of the fourth, and the muscular branches from the plexiform loop of the third and fourth sacral seems to give very good control of the field; and, by supplementing this occasionally with slight infiltration analgesia, dilation of the sphincter and operations in this region can be quite satisfactorily accomplished.

*Journal of the American Medical Association, July 29, 1905.*

**Carcinoma of the Breast.**—Willy Meyer reports ten years' experience with his method of radical operation for this condition. He gives in detail the technique of the operation, and describes at some length the after-treatment of these patients. Meyer claims for this method of operating that the functional result is better than after other operations, as perfect mobility of the arm invariably follows. He reviews the results obtained in seventy cases.

**Tetanus.**—J. M. Anders and A. C. Morgan give a preliminary report of their statistical study of 1,201 cases of tetanus, collected from the literature and by direct correspondence, with special reference to the incidence of the disease in the United States. They find convincing proof that tetanus is invariably the result of the introduction of the germ, and that the so-called rheumatic or idiopathic tetanus does not exist. They also find that it is endemic in all large centers of population, that in some localities where it was formerly common, notably in Long Island, it has become rare, and that occasional small epidemics, traceable to a definite source, occur in limited localities, as for instance, in hospitals, etc. It appears also that tetanus is more prevalent in the hotter part of the year, that males are more subject to it than females, and that it is less frequent in advanced age. The robust are more susceptible than the weak, and the nervous, than the lymphatic. There is much evidence that the disease is transmissible, and may give rise to epidemics. The germ, Nicolaier's bacillus, is rarely introduced by the alimentary tract, but usually through open wounds, all parts of the body being very susceptible. A number of interesting clinical features observed in the cases collected are related, and it was noticed that the characteristic symptoms, especially trismus, were generally present. The diagnostic importance of the tonic contractions as opposed to the intermittent ones in certain other conditions that simulate tetanus, such as strychnia poisoning, is emphasized. The authors found that their studies supported the earlier ones as regards the mortality, which decreases gradually after the tenth day, and rapidly after the fifteenth. The study showed clearly the value of immediate radical local treatment, and that the most important thing is to open the wound freely in all directions under general anesthesia. Many patients were more or less benefited by the local carbolic acid treatment, and some observers report good results from the local use of ice or freezing mixtures, or treatment in a cold room. For palliative treatment, chloral and the bromids appear to have been most extensively used. Calabar bean has been much employed, and also morphine, which should be used with caution on account of its inhibitory action on the respiratory centers. There is no question as to the value of antitoxin as a prophylactic, the testimony is uniformly in its favor. It should be used in any case in which there is suspicion of tetanus infection. In a well-developed case of the disease it has no appreciable beneficial effect, neither reducing the mortality nor hastening recovery.

**Splanchnoptosis from a Surgical Standpoint.**—James E. Moore states that gynecologists have learned that replacing misplaced pelvic organs and supporting them by mechanical means gives only temporary relief. He discusses at some length the nervous disturbances caused by ptosis of the abdominal and pelvic viscera, and refers to the confusion and misapplication of terms used to designate this condition. He refers briefly to the various etiologic causes assigned to this disorder in the literature, and states that a patient suffering from vague, indefinite symptoms of varying severity should never be pronounced hysterical, dyspeptic, or neurasthenic until visceral ptosis has been eliminated. He discusses the differential diagnosis and reviews the literature on this subject.

*The Lancet, July 22, 1905.*

**Some of the Neuroses of Early Life.**—Henry Ashby, in speaking of the characteristics of a neurosis or psychosis in a child, notes the following: Want of coördination in muscular movements, both reflex and voluntary. Hyperesthesia of motor and sensory centers; a slight stimulus provokes a strong reaction out of all proportion to its strength. Failure of inhibitory control over actions or reflex movements. Exaggerated conscientiousness and contrariness. Certain morbid habits not seen in normal children. Tendency to petit mal and hysterical attacks. The writer declares that these characteristics overlap each other. He refers to various habits, such as nocturnal bed-wetting, and declares that it suggests a developmental failure of the controlling nerve centers which coördinate micturition. Head shaking and nodding are also coördination neuroses associated with purposive or instinctive movements, which become confirmed into a habit. Another group of neuroses of the lower neurons includes spasmodic asthma, recurring fever, recurring vomiting, and, perhaps, diabetes. The writer then turns his attention to some of the minor mental abnormalities of early life which are associated chiefly with the higher level centers. Some children are hypersensitive, shedding bitter tears at trifling causes. One class of children show a want of control, not so much over tempers as over desires. These children want every toy they see, regardless of the rights of others. Yet another class show an excessive inhibition over action and desire. Such children are too good, and very sensitive to reproof. They are morbidly afraid of doing something wrong. The personality of the mother or nurse counts for much during the early months of a child's life. Much depends upon heredity, and much on parents. The writer closes his paper with a plea for hard work and hearty play, a simple and a healthy life, as a cure for the neuroses of the twentieth-century child.

**Three Cases of Separation of the Descending Process of the Upper Tibial Epiphysis in Adolescents.**—G. H. Makins states that although this is not an uncommon condition, it has been generally recognized only since the use of the *x*-ray has become habitual in cases of bone injury or disease. The writer then relates the history of three cases. In two of these a kick was adduced as the original cause of the trouble by the patients themselves, and in two of the cases it was noted that the commencement coincided with the football season. This fact shows the influence of violent contraction of the quadriceps extensor in the causation of the injury. The mischief is primarily confined to the part of the tibial tubercle developed from the epiphysis. The pseudo-inflammatory signs which accompany the injury are noteworthy. There are local swelling, heat, and tenderness in the soft parts overlying and surrounding the tubercle. The underlying bone of the diaphysis also shows signs of rarefaction in an increased transparency. The most characteristic clinical symptom is the "giving way" of the forcibly extended knee. This generally precedes the attacks of pain. Rest and local support are the only necessary means of treatment when the cases are seen early and recognized.

**The Digestive and Other Actions of Apples, Pears, Cherries, Strawberries, etc.**—J. Gordon Sharp calls attention to the important digestive action of these fruits. He declares that the acids of the fruit "fix" the iron contained

in proteid foods, forming organic iron salts, which are broken up lower down in the alimentary tract, and which can be employed by the blood tissue. Thus a suitable régimé, consisting of proteid and a reasonable supply of fruit, may "cure" the condition of anemia. The second property possessed by many of the succulent fruits depends upon the ferment or ferments. The writer refers to ferments analogous to those found in the pancreas. He states that many common fruits contain ferments, which play the part of papaine and bromeline (the ferment of pineapple), and that they can digest both egg and serum albumin to some limited extent. The writer then appends an account of various experiments that he has performed in relation to the digestive action of the soft fruits. He states also that to obtain most benefit from these fruits they should be eaten at the end of the chief meal. There are a few exceptions to this general rule. All tinned fruits are inert as digestives, since the high temperature has destroyed their ferments. However, baking or stewing fruits does not entirely destroy the ferment unless the heat be very prolonged.

**Oral Sepsis as a Cause of Iritis.**—E. Kenneth Campbell believes that the ascription of any particular disease to syphilis is often a mere refuge for one's ignorance. "Rheumatism" is an indefinite word, having no precise scientific meaning. The writer states that he has never known a case of rheumatic fever to be complicated by iritis. He also says that there is a lack of scientific evidence of any real etiological connection between iritis and gonorrheal synovitis. The writer has recently seen three cases of iritis in which there was an absolutely negative history of syphilis or rheumatism in any shape or form. In all the three there was marked evidence of oral sepsis; the gums bled easily, pyorrhea alveolaris was present, and the breath had a sour smell. The mouth in these cases was rendered as pure as possible. This treatment combined with mudriatrics and tonics cured all the three cases rapidly. The writer emphasizes the importance of oral sepsis in these cases.

**Twenty-nine Years of Catheter Life.**—R. Hingston Fox reports this case. The patient was a large man. He had been used all his life to outdoor pursuits. When about sixty years of age, he began to have difficulty in passing his urine. Examination showed that the prostate gland was enlarged, but a catheter was passed without difficulty. The patient soon learned to use the catheter for himself, and from this time to the end of his life (twenty-nine years) he never passed more than a few drops of urine without its aid. He took little or no precautions against sepsis.

*Münchener medizinische Wochenschrift, July* 11, 1905.

**The Morphology of the Cytorrhyctes Luis.**—Siegel describes the methods to be employed for the demonstration of the flagellates, which he considers as the cause of syphilis. Only the highest powers of the best apochromatic lenses will do, and bright artificial light is necessary. Before studying syphilitic blood it is better to observe some preparations of normal blood, in order to be able to recognize the various artefacts produced by the disintegration of the erythrocytes, leucocytes, and blood plates. In syphilitic blood the organisms appear as minute highly refractile bodies in very rapid and erratic motion. They vary in diameter from one-half to two and a half microns, and it can be seen that the larger ones are pear-shaped. As the preparation dries nuclei appear, and seem to contain from two to sixteen more refractile dots. The organisms are to be found also in the blood of inoculated monkeys, and appear in the greatest number in the second and third weeks, after which they gradually diminish again. The process of staining, which is very difficult and complicated, is also described, as well as the preparation of sections. These must be extremely thin, those from which the author's drawings are made measuring only two $\mu$ in thickness. He says that so much practice is required for the demonstration of the parasites that he does not expect immediate confirmation of his results, but he claims that if sought for at the proper time it can be found not only in the primary lesions, but in every drop of syphilitic blood, as well as in that of infected animals.

**Critical Observations on the Spirochæta Pallida in Syphilis.**—Thesing brings up numerous objections against the assumption that the spirochæta pallida is concerned in the etiology of syphilis. He first endeavors to show that the spirochæta is not a protozoon but a typical bacterium, since it has neither nucleus, flagella nor undulating membrane. The differential points given by Schaudinn and Hoffman are inadequate, since refractoriness to stains and the sharpness of the spirals are insufficient basis on which to erect a new species, and he reproduces their own photographs in order to show the variety of forms adduced by them as belonging to the same class. Numerous harmless spirochetæ are to be found in smegma, about the anus, and in the mouth, and it is hardly possible by morphology alone to distinguish these from the spirochæta pallida. In the preparations presented by Schaudinn and Hoffman numerous other bacteria and molds, even the cytorrhyctes luis of Siegel, are to be seen, yet if these are accidental contaminations there is no evidence that the spirochæta is not also one. He also points out that it is possible that there may be bacterial contaminations in the stain used, which forms a good culture medium. As it is perfectly possible that it may be only a harmless saprophyte, he believes that much more evidence is needed before the spirochæta pallida can be accepted as the cause of syphilis. He draws attention to the fact not generaly known, *viz.*, that Schaudinn and Hoffman were commissioned by the Government to study the question of the cytorrhyctes luis of Siegel, yet no mention whatever of this organism is made in their report, notwithstanding the fact that it appears in their own photographs side by side with the spirochæta pallida.

**The Avoidance of Renal Irritation in the Administration of Large Doses of the Salicylates.**—Frey discusses the deleterious action of the salicylates, especially on the kidneys, when given in large doses, and describes experiments undertaken on dogs, rabbits, and on himself, in order to determine the best method of counteracting this untoward action. Acting on the assumption that the local irritation of the kidneys as evidenced by the presence of albumin and casts in the urine was due to the acid reaction of the urine whereby salicylic acid was enabled to act directly on the kidneys. He tried the experiment of rendering the urine alkaline by giving alkalides, together with salicylates. It was found that in this way the kidneys could be protected perfectly, while the theapeutic effect of the drug is unchanged, and he therefore recommends that this plan be followed whenever energetic treatment with salicylates is necessary. Alkaline waters are particularly suitable for the purpose, as they also promote diuresis, and the author thinks that gastric irritation will be checked, as well as that of the kidneys.

*Deutsche medizinische Wochenschrift, July* 13, 1905.

**Death During Morphine-Hyoscine Narcosis.**—Landau, in discussing this method of anesthesia, which has been highly vaunted by some of its advocates, says that Bakes is justified in characterizing it as uncertain and dangerous. The earlier reports were very favorable to the method, but numerous fatalities have since been described, and the author quotes a considerable number of these. It appears that the published statistics indicate the extreme mortality of one per cent. for the method, and it is likely that many fatal cases never have been made public. His own fatal case was the eighteenth in which morphine-hyoscine had been used by him, and the patient was a man of sixty-six, who, except for slight arteriosclerosis, gave no evidence of bodily infirmity. The operation was for hemorrhoids, and was performed without complications, 3 cg. of cocaine being used locally. Two and a half hours after the operation there was cardiac collapse, promptly followed by death, in spite of all efforts at resuscitation. In this case only 2 cg. of morphine and 9 mg. of hyoscine were given. The manner in which the toxic effect of these two supposedly antagonistic drugs becomes active is uncertain, and must be settled by animal experiment, though it is doubtful whether the method can ever be rendered a practical one.

**The Surface Tension of Body Fluids Under Physiological and Pathological Conditions.**—Bickel considers that the determination of surface tension of the various body fluids is capable of yielding useful information in regard to diagnosis and pathology. The surface tension of a fluid is the result of the power of cohesion, which draws inward the particles forming the surface, and this is different for different fluids. The surface pressure is represented by the difference between the superficial tensions of two fluids that are in contact or separated by a membrane. The author's experiments were made on the fluids of animals in the normal state, and after they had been modified by artificially induced disease. The results showed that the surface tension of normal blood is fairly constant, but that in factitious uremia it decreases. The surface tension of the tissue juices obtained by expression from the muscles of previously exsanguinated animals is less than that of the blood, but fluctuates between definite limits. In artificially induced gastritis the surface tension of the gastric juice drops below the normal, but as recovery follows it returns to the normal.

**The Preservation of the Sphincter in the Extirpation of Rectal Carcinoma, and its Subsequent Function.**—Kraske takes issue with those operators, especially Witzel, who contend that it is useless to attempt to preserve the sphincter in operations for the removal of malignant growths of the rectum. The principal claims made for this latter method of procedure are that total amputation of the gut is easier, less complicated, and less apt to be followed by infection or hemorrhage than resection, leav-

ing the sphincter intact. It is also stated that the sphincter, even if preserved, is likely to be unsatisfactory; that it is extremely difficult to obtain primary union of the intestinal wound, and that troublesome fistula are likely to persist. Kraske refutes all these arguments, and says that the advantage of preserving the sphincter is of such incalculable benefit to the patient that no technical difficulties should be allowed to stand in the way of securing it. He says that he would rather save the lives of eighty per cent. of his patients with a sphincter than eighty-five or ninety per cent. without it. In regard to the efficiency of anal continence after the operation, he gives in brief the histories of fourteen cases, all operated more than three years ago, and who have enjoyed perfect control of the sphincter ever since. In performing resection a somewhat greater degree of care is necessary to secure perfect asepsis and primary union of the intestinal stumps, but a perfect result can be obtained, and means so much to the patient that all drawbacks are compensated for a hundredfold.

*The American Journal of the Medical Sciences, June,* 1905.

**Croupous Pneumonia.**—Thomas G. Ashton and H. R. M. Landis present a report of 991 cases of croupous pneumonia; of these 757 were males and 234 females. The mortality for the whole series of cases was 53 per cent, the total number of deaths being 533. This extraordinarily high death rate is accounted for by the class of patients from which these statistics are derived, for these patients were the riff-raff of society. Considerably more than half of the cases occurred during the cold and changeable months of the year. Of 900 of these cases, the right lung alone was involved in 487; the left alone was involved in 293; both lungs were involved in 120. Of the 991 cases, 104 were alcoholics. In a certain proportion of the cases, not large, injury especially to the chest bears a causal relation to the development of pneumonia. This relation was indirect, showing itself in decreased tissue resistance and in the increased virulence of pneumococci already present. In a large proportion of cases a chill marks the onset of pneumonia. In 679 of the cases the peculiar stabbing pneumonic pain was present; cough was noted in 737 cases. The crisis occurred on the odd days in 152 of these cases, and on even days in 112. The usual leucocytosis ranged from 10,000 to 40,000. The course of these cases, as the writers state seems to have been practically uninfluenced by any particular plan of treatment, for no matter what treatment was adopted, the mortality seemed to remain about the same.

**Peripheral Obliterating Arteritis as a Cause of Triplegia Following Hemiplegia, and of Paraplegia.**—Charles W. Burr and C. D. Camp describe a patient, who was the subject of a not very infrequent but much neglected form of palsy, caused by obliterating arteritis in the extremities affected. The patient was a man, seventy-eight years old. The writers sum up the case as follows: There was moderate dilatation of the lateral ventricles, some degeneration of the posterior columns of the cord, great general arterial sclerosis, so marked in the right posterior tibial artery as almost to occlude it, while the left was completely closed by an organized thrombus, muscular atrophy, and degeneration of the peripheral nerves. The changes in the spinal cord were not sufficient nor of a nature to have caused paralysis of the legs. The changes in the muscles and nerves surely resulted from the vascular disease. The case, then, was one of senile paraplegia, caused by obliterating arteritis. This condition may come on slowly with dull pains in the legs, paresthesias, and gradual loss of muscular power. If thrombi form, the onset may be sudden, and gangrene may supervene. Intermittent lameness occurs in the earlier stages in many cases.

**Some Phases of the Neurotic Heart.**—Beverley Robinson specially emphasizes the following facts in relation to this affection: An apparent or evident slight cardiac enlargement, with or without dilatation, and it may be slight hypertrophy, occasioned by or proceeding directly from a cardiac neurosis. A condition of secondary anemia, as shown by careful microscopic blood examination, with count and differentiation of white corpuscles, which remain stationary for a long while, despite the use of chalybeates, and most rational tratment from every standpoint. The absolute or relative uselessness of digitalis, notably, unless the heart muscle is involved, and even in these instances, for acute manifestations of weakness or failure, strophanthus is far more useful. Impaired nutrition, at a given period, of the muscular walls of the heart under the immediate dependence, probably, of diminished nervous energy, give rise to slight cardiac dilatation at times which subsequently, under judicious treatment, remains stationary as to amount, and becomes functionally compensated.

**Acute Flexion (Jones' Position) in the Treatment of Supracondylar Fractures of the Humerus.**—Astley Paston Cooper Ashhurst cites a case of supracondylar fracture of the left humerus. The patient, a girl nine years old, received this injury by falling from a chair to the floor. A skiagram confirmed the diagnosis of supracondylar fracture. In accordance with the indications, the lower fragment being still posterior, and tilted upward by the action of the triceps, the forearm was actually flexed on the arm into Jones' position, and maintained by the usual bandages, the wrist being slung close to the patient's neck. The swelling was very great, and some pain was caused by forced flexion. The writer was careful to see that the radial pulse was not obliterated, and the pain ceased in a short time and did not recur. There are many advantages claimed for the position of acute flexion in such cases; it both effects reduction and maintains it. The coronoid process of the ulna rises up and locks against the lower end of the upper fragment and acts as a splint, for it prevents the displacement of the intervening fragment; and the position is an easy one for the patient. No splint is required, and the arm is not bound to the side. Ankylosis is far less apt to occur. The writer adds that if in adults the deformity can be overcome and reduction maintained with the elbow at right angles, he prefers to treat these patients in that position; however, this is often impossible.

**Hypernephroma: Report of Three Cases.**—Isabella C. Herb declares that until embryologists decide where to classify a certain new growth found in the kidney, the term hypernephroma is a happy one. It is a debatable question whether these tumors are to be placed with the sarcomas, carcinomas, or adenomas, and it will depend upon whether one makes morphology or hystogenesis the basis of classification. There is no question as to the malignancy of these neoplasms. Metastasis takes place through the blood current. The writer reports several of these cases. She describes the gross appearance of two of the tumors as follows: They are very nodular, with large, engorged vessels passing in all directions over the surface. The capsule, to which considerable fat is attached, is firmly adherent; the cut surface is strikingly uniform. Bands of tissue, salmon-pink in color, support islands of tissue of various hues. No cysts were present, and no kidney structure could be demonstrated. Microscopically, sections taken from all parts of the tumor show the typical structure of the adrenal cortex, both in their architecture and the relation of the cells to the blood vessels.

**The Problem of the Treatment of Laryngeal Tuberculosis.**—W. B. G. Harland believes that over one-fourth of all cases of clearly defined pulmonary tuberculosis present laryngeal lesions. It is supposed that the greater number of laryngeal cases are due to infection from the lungs carried in the sputum, or through the lymph or blood vessels. The structures most often attacked are the vocal cords, interarytenoid fold, and arytenoids. However, any and every part of the larynx may be attacked by the tuberculous process. The manifestations of laryngeal tuberculosis other than miliary are seen in four forms: Superficial ulcer, infiltration of mucosa, tuberculoma, and deep ulceration. A satisfactory diagnosis of the local disease is not possible without a laryngoscopic examination. The patient must be studied as a whole in order to estimate the progress of the disease. The writer describes this infection as an insidious, intractable, subepithelial infection, the germs of which lie hidden in and beyond the limits of apparent disease. Treatment is directed toward liquefying and removing secretions from the upper air tract, relieving congestion and lessening irritation, and toward destroying tubercle bacilli and the diseased area produced by them. General treatment is most important in all cases.

**Tuberculosis of the Prostate.**—Thomas R. Crowder says that prostatic tuberculosis is not a rare disease. Various authorities differ in their opinions as to the starting point of the disease in the genitourinary organs; although primary prostatic tuberculosis is exceptional and relatively rare, its existence is well established both from a clinical and pathological point of view. Tuberculosis of the prostate begins most often in early adult life, attaining its maximum frequency between the ages of twenty and forty years. Heredity plays an important part. The one etiological necessity is that the tubercle bacillus shall find its way into the gland. This takes place generally by the direct implantation of the tubercle bacilli from the blood or lymph stream. If a tuberculous focus exists deep within the substance of the prostate it may remain long without symptoms. Subjective symptoms generally develop sooner or later, often quite suddenly as the result of abuse, exposure or venereal infection. The diagnosis of tuberculosis of the prostate cannot usually be made from symptoms alone. The condition of the urine varies greatly, according as to whether or not, and to what extent, the bladder is involved. Tuberculosis of the prostate is always a grave disease. The rapidity of the course depends upon whether the general health, strength, and habits of the patient are good, and whether the disease is local, or only the part of a

diffuse infection. In a small number of cases tuberculosis of the prostate is amenable to surgical treatment. Various forms of local treatment other than operative have been tried with varying success. The general treatment is that of tuberculosis in other parts of the body.

*French and Italian Journals.*

**Race Psychology in Its Relation to the Accidents of Workmen.**—Blind has undertaken various researches, in order to discover whether different races show a different psychical reaction in the case of accidents occurring during work. He has studied the cases of eight hundred and six Alsatian men, ninety-nine Alsatian women, and fifty-one Italian men. The ages of these subjects varied all the way from twenty to sixty years. In the case of the Alsatian men, the different forms of traumatic neurosis amount to 6.6 per cent.; in the Alsatian women, to 12.1 per cent.; but in the Italian men the percentage was far higher, reaching 39.2 per cent. This preponderance of traumatic neuroses in Italian workmen is certainly due to a predisposition of the Latin race to these diseases.—*Le Bulletin Médical,* June 10, 1905.

**Cancer of the Esophagus.**—Agasse-Lafont reports this case. The patient suffered in the last weeks of his life from very frequent and very abundant hemorrhages, a rather rare occurrence in cancer of the esophagus. He died from these hemorrhages, which no treatment could arrest. At autopsy two cancerous foci were discovered. The first one was situated seven centimeters above the cardiac opening; it involved the entire circumference. It was five centimeters in length, and almost occluded the lumen of the tube. The second focus was above the first and was separated from it by a space of two centimeters. This neoplasm was of recent origin. It occupied only the anterior wall, which was dilated at this point. It was eight centimeters long, by four wide. The center was depressed, bloody, and very vascular. The hemorrhages had come from this point. It is interesting to note that the secondary focus was above the primary one. The fact is explained by the presence of a marked stenosis and a consequent adjacent dilatation. During the attacks of vomiting, bits of cancerous tissue were detached from the primary tumor and were carried into the dilated portion of the esophagus, where they attached themselves and formed a secondary growth. Histological examination showed this tumor to be an epithelioma.—*Bulletins et Mémoires de la Société Anatomique de Paris,* March, 1905.

**Paget's Bone Disease Cured by Antisyphilitic Treatment.**—Jacquet had this case under his care. The patient, when in full health at the age of fifty-three years received a severe injury to his right tibia. The shock was so great that the patient lost consciousness. Nevertheless, there was neither wound or fracture. Several months later, however, acute pains developed in the right leg with a sensation of heat, soon followed by deformity and swelling of the region. Now, three years after the accident, there is a distinct deformity of the type of "saber scabbard." There was at once suggested the presence of a bony lesion of syphilitic origin, and in spite of the absence of certain antecedents antisyphilitic treatment was instituted. The results were rapid and marked. Pain and functional impotence ceased. The writer believes that this was a case of Paget's bone disease due to a former traumatism; its syphilitic origin seems at least possible, after noting the rapid effect of specific treatment.—*La Presse Médicale,* July 5, 1905.

**Hypertrophic Acne of the Nose.**—Cléjat was interested in this case. The patient was a man sixty-five years old, a smith by trade. Thirty years ago he noted the development of several points of pustulous acne on the lobule and the wings of the nose. The skin of the nose soon thickened, becoming irregular and knobby. At the end of fifteen years the nose was about the same size as it was when the patient presented himself for treatment. The nose was transformed into a bosselated mass. The lobule itself was as large as a nut. The skin looked like that of an orange, and was sprinkled with comedones and fatty cysts. The tumor was indolent and of soft consistence. By palpation the cartilages could not be felt. This may have been due to the fact that they were masked by the thickness of the tumor—or, what is more probable, that they had undergone a diminution. On account of the thickness of the tumor, respiration was considerably impeded; this was especially noted on the left side and when the patient was lying down. Operation was undertaken. The thermocautery was first used, followed by dissection with the histoury. Although the nose was greatly diminished in size, it remained full large enough, for it was impossible to take away any more tissue on account of the amplitude of the cavities.—*La Médecine Moderne,* July 5, 1905.

**Antibacterial Serum in the Treatment of Diphtheria.**—Luigi Concetti draws our attention to the fact that in spite of the use of antitoxin, there are still a considerable number of deaths from diphtheria. The death rate would be reduced were all cases coming in contact with patients immunized, but there would still remain cases of mixed infections, which are very fatal because the virulence of the Loeffler bacillus exalts that of the complicating bacteria. In other cases there seems to be in the beginning an extreme degree of virulence of the infection, which overpowers the child before antitoxin can take effect. But the most important element in the causes of death is the fact that, although the toxins are counteracted, there still remain the bacilli, living, or the poisoning due to the presence of their dead bodies. Antitoxin counteracts only the soluble poison produced by the bacilli, and has no effect on the bacilli themselves. Bandi and Wasserman have, by different methods, produced a serum that is also active against the bacilli themselves. This antibacterial serum may be applied locally to the throat, to the conjunctiva, when that is affected, or to the nares as a prophylactic for those exposed to contagion. It may be introduced into the circulation so as to counteract the bacteria contained in the blood and internal organs. When the serum injected has the properties of antitoxin and antibacterial qualities combined, that is a bivalent serum, we get results superior to those of antitoxin alone.—*Rivista di Clinica Pediatrica,* June, 1905.

**Clinical Experience with Bivalent Antidiphtheritic Serum of Sclavo-Bandi.**—Maurizio Pincherle has used the bivalent antidiphtheritic serum of Sclavo-Bandi, which is antitoxic and antibacterial, in fifty-three cases, of which he gives us an account. There are two sera on the market—one for use by injection, and one rendered more active by the presence of very energetic antseptic substances, which is to be painted locally on the initial foci of the disease. There are also pastilles to be dissolved in the mouth. The author has found the serum of marked value in all classes of cases, severe, complicated with stenosis, or slight, and even in the severest forms of infection, and where delayed treatment has rendered them almost hopeless. He concludes as follows: 1. This treatment has exerted a rapid and effective therapeutic action in anginal or croupous cases, not complicated by lack of organic resisting power, or profound toxic phenomena. 2. It has been useful as an adjuvent to the antitoxic treatment, except in the most inveterate cases, even when the organism was severely intoxicated. 3. The serum locally applied seems destined to exercise a double action, preventive and prophylactic, of the greatest importance in preventing the diffusion of the morbid process.—*Rivista di Clinica Pediatrica,* June, 1905.

**Suture of the Heart for Hemorrhage.**—Giovanni Casapinta gives us his opinion as to the value of cardiac suture in cases of wound of the heart, and the technique that should be observed. He calls our attention to the fact that the amount of hemorrhage is not an index of the severity of the wound. The obliquity of the wound, the formation of a coagulum in it, or of a parietal thrombus, assisted by syncope, the arrest of the instrument in the wound, proximity to a columna carnea, may prevent the emptying out of blood externally. No distinction should be made, in regard to operation, between penetrating and non-penetrating wounds; operation is demanded in all cases of wound of the heart. The first consideration should be the immediate arrest of hemorrhage, to prevent fatal anemia. The hemorrhage should be stopped at once by the use of forceps, and the author has constructed one with long blades at an angle with the handle, provided with teeth to grasp the heart muscle. General anesthesia should be used; as strict asepsis should be maintained as the necessary haste will permit. The trans-pleural route has the advantage of permitting the renair of the accompanying lesions, the lung generally being wounded also; and the opening should be large enough to permit of easy suture of the heart. When the wound is near the sternum it must not be enlarged toward the right, lest we get a fatal double pneumo-thorax. Silk should be used for the sutures, since catgut is too soon absorbed. The heart action will remain irregular for some time after suture, and digitaline may then be given.—*Giornale Medico del Regio Esercito,* June, 1905.

---

**Diacetic Acid in the Cerebrospinal Fluid in Diabetes.**—Grünberger describes a case of diabetic coma occurring in a girl of 16, whose symptoms were alleged to have begun only eight weeks previously. The urine contained large amounts of acetone, diacetic acid, and $\beta$-oxybutyric acid. On examining some of the cerebrospinal fluid obtained by lumbar puncture, diacetic acid was found, as well as other peculiarities in regard to sugar content and freezing point, which are not described. The author says this is the first described case in which this observation has been made.—*Zentralblatt für innere Medizin*

# Book Reviews.

Diseases of the Blood. By Dr. P. Ehrlich of Frankfort-on-the-Main; Dr. A. Lazarus of Charlottenburg; Dr. K. von Noorden of Frankfort-on-the-Main, and Dr. Felix Pinkus of Berlin. Edited, with additions, by Alfred Stengel, M.D., Professor of Clinical Medicine, University of Pennsylvania. Philadelphia and London: W. B. Saunders & Company, 1905.

The English translation of Nothnagel's Practice is now nearly completed. The volume before us treats of Diseases of the Blood, and is the work of four German specialists. The first part on Histology of the Blood, Normal and Pathological, is by Drs. Ehrlich and Lazarus. Here the well-known views of Ehrlich and his school are skilfully set forth, and the editor has done good service in giving space to the opinions held by other writers. Dr. Lazarus is also responsible for the article on the Clinical Features of Anemia. The section on Progressive Pernicious Anemia is particularly full and satisfactory. The part dealing with Chlorosis is from the pen of Dr. von Noorden, and is the longest and most thorough treatise in the volume. He devotes special attention to questions of etiology and symptomatology. The author has decided views on sex as a predisposing cause of Chlorosis. Fortunately, the editor here again tones down the dogmatism of the author and gives fair consideration to the opinions ignored by the latter. Dr. Pinkus is responsible for the chapter on Lymphatic Leukemia; and that on Myeloid Leukemia is the work of Dr. Lazarus. Editorial additions have been made wherever it was necessary to bring the original articles up to date, and also in several instances where the authors ignored too much those who differed from them. Dr. Stengel has, in this volume, accomplished a difficult and delicate task with consummate skill, and his editorial notes are of more than ordinary value. There is an unfortunate transposition of several lines on page 616.

The Development of the Human Body. A Manual of Human Embryology. By J. Playfair McMurrich, A.M., Ph.D., Professor of Anatomy in the University of Michigan. Second edition, revised and enlarged; with 272 illustrations. Philadelphia: P. Blakiston's Son & Co., 1904.

This book on Embryology consists of two parts, the first of which contains five chapters and deals with general development. The second part, which forms by far the greater part of the volume, considers in detail the development of the various tissues, organs, and systems of the body. There are chapters devoted to the integumentary system, the connective tissues and the skeleton, the muscular system, the circulatory and lymphatic systems, the digestive tract and glands, the pericardium, pleuro-peritoneum, diaphragm and spleen, the respiratory organs, the urogenital system and the suprarenal bodies, the nervous system, and the organs of special sense. The volume concludes with an important chapter on post-natal development. At the end of each chapter is a brief but recent bibliography. The general plan of the book is the same as in the former edition, and the only changes are such as have been rendered necessary by recent contributions to Embryology. The book contains numerous illustrations, and these are unusually clear and instructive.

Recherches Cliniques et Thérapeutiques sur l'Épilepsie, l'Hystérie, et l'Idiotie. Compte-rendu du service des enfants idiots, épileptiques et arriérés de Bicêtre pendant l'année 1903. Par Bourneville, avec la collaboration de J. Boyer, L. Izou, Lemaire, Reine Maugeret (Mlle.), Julien Noir, Paul-Boncour. Volume XXIV., avec 72 figures dans le texte et 17 planches. Paris, Felix Alcan, 1904.

The first part of this volume gives a *résumé* of the hospital service at Bicêtre and Fondation Vallée, for the year 1903. The remainder deals with various conditions more or less connected with idiocy and epilepsy, and the histories of the cases are given in considerable detail. The most important contribution is that by Drs. Bourneville, Lemaire, and Maugeret, on the different forms of nanism, and the treatment of the same by thyroid extract.

A German-English Dictionary of Terms Used in Medicine and the Allied Sciences. By the late Hugo Lang, B.A. Edited and completed by Bertram Abrahams, M.B., B.Sc., F.R.C.P. Assistant Physician, Westminster Hospital; Sub-Dean and Lecturer in Physiology, Westminster Hospital Medical School; Examiner in Physiology to the Conjoint Board. Philadelphia: P. Blakiston's Son & Co., 1905.

It is doubtful whether a perfect dictionary of German medical words ever can be compiled, but the present volume comes quite close to achieving the impossible. Its sins, both of omission and commission, appear to be very few, and the number of words not strictly medical included is large enough to help even an indifferent German scholar over many difficulties. The typography is extremely well adapted to its purpose, and the binding is unusually ornamental. The work is certainly the most satisfactory one of its kind that has recently appeared, and it may safely be commended to those interested.

Outlines of Inorganic Chemistry. By Frank Austin Gooch, Professor of Chemistry in Yale University, and Claude Frederic Walker, Teacher of Chemistry in the High School of Commerce of New York City. New York: The Macmillan Company; London: Macmillan & Co., Ltd., 1905.

The authors of this excellent book have almost succeeded in making the study of chemistry easy, and they have done even better—they have made it interesting to the beginner and to the man who would know the principles of this science and its main facts without burdening his mind with the mathematics of chemistry. The first part deals with the principles upon which chemistry rests. This embraces a consideration of the identity of substances, chemical change, the elements, the laws of combination, and chemical equivalents. Then follows an explanation of electrical phenomena, ions, the constitution of acids, bases, and salts, action and equilibrium, and the thermal relations of chemical action. The discussion of the properties of elements and their compounds is taken up in Part II., the elements being arranged in groups and series after a modification of Mendeléeff's periodic system.

The book is one which seems to the reviewer peculiarly adapted to the needs of the medical student who must know the principles of this science but who does not intend to be a practical chemist. It will also be very useful to the practitioner of medicine who may have acquired a smattering of chemistry in his student days—which he has probably forgotten—but who wishes to know something of the modern science in order to understand the relations of chemical action to electricity and to read intelligently of the phenomena of radioactivity. The language of the authors is so straightforward and clear, and the complex chemical phenomena are described and explained in such simple terms, that no one of ordinary intelligence can fail to comprehend them.

Atlas and Text-Book of Topographic and Applied Anatomy. By Oskar Schultze, Professor of Applied Anatomy in Würzburg. Edited, with additions, by George D. Stewart, M.D., Professor of Anatomy and Clinical Surgery in the University and Bellevue Hospital Medical College, New York. With twenty-five colored illustrations on twenty-two Lithographic Plates, and eighty-nine Text-Cuts, sixty in colors. Philadelphia and London: W. B. Saunders & Co., 1905.

In a handy volume, prepared especially for the medical practitioner, the author presents us with the essentials of regional anatomy, and a finely illustrated atlas of the same. The whole ground of the subject is gone over, but, by careful elimination of all except the most important facts, the book has been kept within the reasonable limits of one hundred and ninety small quarto pages; and it is, in fact, one of the few handy atlases dealing with the subject. The plates are magnificent, and are free from the usual blemish of being overloaded with details and names. The editor has added occasional notes, which materially increase the value of the volume. We wish that he had not been quite so sparing with his annotations; *e. g.* a few lines on the regions of the abdomen as understood by American and English readers, would have been of service. A few slips have been noted. On page 41, the parotid duct is made to open opposite the second upper bicuspid (on page 54 it is given correctly); Woolsey's name is invariably misspelt; the legend to plate 19 describes it as a "male pelvic outlet," yet we find Bartholin's gland, glans clitoridis, labium minus, vestibule of the vagina; plate 20, which claims to be a "female pelvic outlet," contains a corpus cavernosum of the penis. But these are mere flaws on a capital piece of work, and no one will be misled by them.

The Medical Epitome Series. Clinical Diagnosis and Urinalysis. A Manual for Students and Practitioners. By James R. Arneill, A.B., M.D., Professor of Medicine and Clinical Medicine in the University of Colorado, Physician to the County Hospital and to St. Joseph's Hospital, Denver. Series edited by Victor Cox Pedersen, A.M., M.D. Illustrated with 79 Engravings and 1 Colored Plate. Philadelphia and New York: Lea Brothers & Co., 1905.

This volume contains the essentials of laboratory examinations and diagnosis, and includes the following subjects: Blood, gastric contents, feces, sputum, urine, cerebrospinal fluid, etc. The book is intended for physicians and students, and the author is to be congratulated on having prepared a book that is so eminently practical and useful. The careful selection of the various procedures, and the judicious omission of many time-wasting processes make this volume of more than ordinary value.

# Society Reports.

## AMERICAN SURGICAL ASSOCIATION.

*Twenty-sixth Annual Meeting, Held at San Francisco, California, July 5, 6, and 7, 1905.*

PRESIDENT, DR. GEO. BEN JOHNSTON OF RICHMOND, VA.

The Association held its sessions in the banquet hall of the St. Francis Hotel.

After a brief executive session, Dr. Emmet Rixford of San Francisco, first vice-president, took the chair, and the president delivered his address.

**John Peter Mettauer.**—Dr. GEORGE BEN JOHNSTON selected as the subject of his annual address a sketch of John Peter Mettauer. He said that little was known of his childhood and youth beyond the fact that, raised in an atmosphere of surgery, he imbibed a love for this profession, and early determined to adopt it as his life's work. He was born in 1787. Mettauer's medical education was carried on under the most favorable conditions obtainable in America at that time. For a period of about forty years the number of surgical patients who gathered to Mettauer for treatment was sufficient to keep him constantly with from 45 to 60 cases under his care. Often it was true that about every good house in the community sheltered some person who was convalescing or awaiting his turn for operation. The speaker had heard his operations for cataract put in number far beyond the 800 that could be accounted for. Dudley's great record in cutting for stone 225 times in a practice of forty years must yield to Mettauer's total of 400 operations, and the number of strictures relieved was commonly put at something over 200. Three operations were recalled, performed in the last week of his life, when at the age of 88 his eyes were yet keen enough and his hands steady enough for him to make a successful operation for cataract, for stone, and for amputation of the breast. But Mettauer's most brilliant work in the way of operations was his method with vesicovaginal fistula, and his successful employment of wire sutures made of lead, in which he antedated by a good many years even Sims, whose name was generally associated with this operation. So successful was Mettauer that he declared his belief that every case of this sort was curable by his method, and so far as his efforts were reportsd, the speaker was not aware that he ever failed in one. Proper pride and regard for his own reputation in the coming years must make every surgeon careful to a degree in assigning credit for useful and honorable achievements to those who had preceded him, and there was in the history of surgery no claim more clear and unmistakable than that of John Peter Mettauer to the honor of discovery in this case, and he was plainly entitled to rank in medical history and in the grateful memory of his successors in the same class with McDowell and Dudley and Sims and Mott. Mettauer's first reference to the operation of vesicovaginal fistula appeared in the *Boston Medical and Surgical Journal*, Vol. 22, page 154, twelve years before Sims' communication, and it clearly outlined the operation which ought always to be associated with his name. Mettauer was decidedly of the opinion that every case of vesicovaginal fistula could be cured, and his success justified the statement.

Reference was made to the eccentricities of Mettauer, and among them was his invariable custom to wear on all occasions and at all times a preposterously tall hat. One of his children, now surviving, had told the speaker that she never saw her father without his hat on. He never attended service in the churches, and the explanation was always assumed to lie in the unwillingness either to remove the covering from his head or to attend church wearing his hat. He would decline to take off his hat in court on the occasions when his expert testimony was sought, and the sole occasion on which a judge seems to have insisted that the doctor should be uncovered brought from Mettauer the suggestion that if his evidence was essential to the cause he would be pleased to give it with his hat on, and that if it were not so, he would be quite as well pleased to leave the courtroom—meanwhile, of course, wearing his hat.

Dr. Johnston said that so great was his interest in seeing full justice done to the genius of Mettauer that he was seriously contemplating some extended work in the way of a biography.

**End Results in Surgery of the Kidney, with Report of Ninety Cases and One Hundred and Twenty-three Operations.**—Dr. ALBERT VANDER VEER of Albany, N. Y., read a paper on this subject, which was based on a review of ninety cases occurring in his own practice. The next largest group was composed of movable or floating kidney. These numbered twenty-three cases, exclusive of those where excision of the capsule for neuralgia, examination for stone, and decapsulation for Bright's disease were done. Nineteen of these cases occurred in women, about two-thirds of whom were married, the lesion being on the right side. There were four males, the lesion also occurring on the right side, and the entire number recovering. One required removal of the kidney four years after for abscess of the pelvis and stone; good recovery. He next presented a series of twenty-four cases of nephrotomies, in which there was a surgical lesion of the kidney, grouped under the headings of pyelitis, pyonephrosis, pyonephritis, and ascending pyelonephrosis. The series was divided as follows: Male, right side, two recovered, one died; male, left side, six recovered. Nine of these cases finally required nephrectomy, one of the latter resulting in death. Of the remaining fifteen cases, all made good recoveries; but one of them, after a period of four years, had a slight sinus—not deep, no pus, patient in excellent condition. The other patient recovered from the kidney complication, but developed a pelvic abscess, which was still draining, and she was gradually losing ground. In the cases of nephrectomies for hydronephrosis there were eight, as follows: Male, right side, two recovered; female, right side, three recovered; female, left side, two recovered, one died. Regarding the removal of the kidney by the transperitoneal incision, the author stated that it was an exceedingly easy and convenient way of removing a large cyst or tumor, the patients doing nicely afterwards. Of these, there were four cases. He then cited two cases of hydronephrosis in young women who were entirely cured by simple aspiration.

Of nephrotomies, followed later by nephrectomies, there were nine cases, as follows: Male, right side, two recovered; male, left side, one recovered; female, right side, three recovered; female, left side, three recovered. All of these cases made a good recovery from the two operations, with the exception of two patients, one dying a few months after from multiple abscesses of the remaining kidney, and the other, still alive, was gradually failing in strength.

The author was greatly impressed with the study of tuberculosis of the kidney, as to whether the invasion occurred from below or from systemic infection. There were seven of these cases, as follows: Male, right side, one recovered; male, left side, two recovered; female, right side, one recovered; female, left side, three recovered. There was a total of eight cases of malignant growths in connection with the kidney, as follows: Sarcoma, male, right side, two recovered, one died; male, left side, one died; female, right side, one recovered; female, left side, one died. Carcinoma, female, right side, one recovered, but died later from return of the disease. Hypernephroma, male, left side, one recovered. Of decapsulation of the kidney for nephritis, there were two cases that recovered; results excellent. Of traumatisms and injuries of the kidney, there were six cases. Of cases of renal neuralgia, associated with suspected stone of the kidney, the author was not able to confirm his diagnosis by exposure of the organ. The entire group was made up of six patients, and in only one instance was the diagnosis confirmed by needling of the kidney.

The author then reported some irregular cases, and concluded his paper by the relation of two cases of abdominal surgery which illustrated errors in diagnosis, in which the real trouble was with the kidney.

In a review of the cases presented in this paper, one was impressed with the very excellent results following the operation of fixation of the kidney. In the hands of all operators the mortality list was exceedingly small. Wearing of a bandage, with kidney pad, was exceedingly irksome to many patients, who gladly consented to surgical intervention when the prospects for recovery were so good.

The combined operation for nephrotomy and nephrectomy later for abscess of the kidney was appropriate for such cases as would not bear too long an operation, and where there might be a large kidney, made up of multiple abscesses in such a way as to make manipulation of the organ quite difficult. Simple drainage benefited the patient for a time, often causing a diminution of the mass to be removed later. In the purely cystic form of kidney, a true pyonephrosis, an immediate nephrectomy was proper in the majority of cases. Following a nephrotomy or nephrostomy a very fair number of cases recovered without further intervention. In a large pus kidney there was always some danger in a nephrectomy of causing an infective peritonitis. In traumatisms of the kidney firmness and decision on the part of the surgeon were an absolute necessity. There were no other forms of emergency surgery more exacting. In cases of movable or floating kidney, giving such marked symptoms that the surgeon was often led to believe that he had a stone to deal with, the speaker admitted that our diagnoses were very far from correct, and the cases here reported were disappointing by reason of not finding a calculus present. It was sometimes difficult to diagnose between a neuralgic kidney and one containing a calculus in its pelvis. Splitting of the capsule relieved pain in cases that could only be classified as a neuralgic condition. It was yet a mooted question as to how much could be accomplished by resection of the kidney for relief of abscesses and growths. The cases of tuberculosis reported manifested decidedly the importance of an early operation, and gave a most encouraging outlook for these patients regarding permanent recovery. Malignant growths gave our mortality list, and yet there was much hope for these cases if reached early. Surgery of the kidney was becoming more and more exact with the splendid advances made in methods of examination of the urine, etc. Errors of diagnosis would occur less frequently in the practice of abdominal surgeons as methods of examination became more perfect. The writer was impressed with the oblique incision, which had been employed in nearly all of his cases during the past ten years. The one case of hernia reported resulted from the old incision, parallel with the spine and transversely through the muscle, causing a lumbar hernia, but none of the others presented this complication. In a total of about 90 patients there were 123 operations done. This was readily accounted for because of the patients requiring more than one operation. The rate of mortality was exceedingly small, malignant disease and abscesses of the kidney being alone responsible.

Dr. William J. Mayo of Rochester, Minn., asked the speaker whether he took out the ureter or considered it necessary to remove it in cases of tuberculosis of the kidney. Also, whether any of the cases in which nephrotomy for tuberculosis of the kidney was performed had been followed by permanently good results. Recently he had gone over the histories of some 36 nephrectomies for tuberculosis of the kidney, and had found that a large number of people who were supposed to have tuberculosis of both kidneys in the early stage had only one kidney involved. Careful examination had shown in the majority of these cases, according to his recent experience, that the tuberculosis was confined to one kidney. He thought a large majority of cases of tuberculosis of the kidney were one-sided to start with; that his experience, as furnished largely from post-mortem examinations, was that the second kidney became involved at the time of death, and that therefore he had post-mortem rather than living evidence of the fact that in the early stages the percentage of cases in which tuberculosis of the kidney was bilateral was small.

Dr. N. B. Carson of St. Louis mentioned a case in which a diagnosis of floating kidney was made by several good surgeons, and he operated with the intention of fixing the kidney. He found the kidney slightly movable, but not floating. Later an eminent surgeon said the case was undoubtedly one of floating kidney, even after the operation had been done. The speaker told this surgeon that he had already fixed the kidney. Later he operated again and instead of a floating kidney found a floating right lobe of the liver. The gall-bladder was enlarged to the size of a kidney. This was fixed to the liver. It contained a number of stones. The right lobe of the liver was so freely movable that the gall-bladder could be floated, so to speak, all over the abdomen, and it so corresponded to the shape of the kidney that every one who examined the patient made a mistake. The floating kidney was removed, and the patient made a good recovery.

Dr. Archibald Maclaren of Minnesota mentioned the ease with which a kidney could be removed after resection of the twelfth rib. He got this idea from Dr. Mayo. He had tried this in a recent case and found he could do the operation more easily by resecting the twelfth rib, although he opened the pleura. The opening in the pleura could be easily plugged with iodoform gauze.

Dr. Vander Veer, in closing the discussion, said, in reply to Dr. Mayo, that the tuberculosis was confined to one kidney in his cases, and he had no record of bilateral kidney tuberculosis. In regard to the removal of the ureter, in the first case he operated upon, he did not remove the ureter, and in one case he had to do a secondary operation on account of relapse. In regard to Dr. Carson's case, he had seen almost a duplicate of it, in that there was a sarcoma which involved the gall-bladder and right lobe of the liver.

**Non-Parasitic Cysts of the Spleen.**—Dr. Charles A. Powers of Denver, Colo., in a paper with this title, stated that this subject had a twofold origin: (1) The few and comparatively recent clinical reports; (2) the somewhat more numerous accidental post-mortem findings. In September, 1895, a young man of 18 was referred to him who presented a large, right-sided, abdominal cyst. The mass was of four years growth. There had been a gradual loss of flesh and strength, anorexia, headache, and general pressure symptoms. Fluctuation was plain. The diagnosis of splenic cyst seemed positive. A free incision was made over the prominent part of the tumor, the walls of which were found to be about one-half of an inch thick, semi-cartilaginous and solidly adherent to all the adjacent structures. Extirpation seemed impossible. Later autopsy findings confirmed this. The single cyst held several liters. A posterior incision was made, with through drainage. The walls of the cyst did not collapse and the patient died of septic absorption from the cyst wall on the twelfth day. The anatomical diagnosis was hemorrhagic cyst of the spleen. From the autopsy findings the author could not see how the cyst could have been successfully extirpated. He presented a brief analysis of thirty-two tabulated cases. In considering the treatment he spoke of puncture, incision and injection, incision and drainage, marsupialization, resection of cyst, and splenectomy.

**Status Lymphaticus and the Ductless Glands.**—Dr. Roswell Park of Buffalo, N. Y., defined the term status lymphaticus, and stated that the reason for bringing the subject before a body of surgeons was because the condition itself had so much to do with the question of toleration of anesthetics, and the matter of repair of wounds, that it really was one of exceeding importance. Not a few cases of sudden death during and after operation were to be explained by the abnormalities constituting this condition. These had usually been attributed to the anesthetic or the anesthetist, and it might be that, had the latter

appreciated all the dangers offered by the condition, he would have guarded his anesthetic, or perhaps abstained from giving it. Nevertheless, the anesthetizer was not always to blame, because he was often called in without previous knowledge of the case, it being really the function of the medical attendant to study it carefully and determine its peculiarities. The relation which the lymphatic system and the lymph-making organs bore to each other and to the ductless glands was as positive as it was obscure. Lymphoid tissue throughout the body seemed to increase as the thymus normally disappeared. In infantile marasmus the thymus had usually completely and prematurely disappeared, its condition being a fair index as to general nutrition. But it was hypertrophy rather than atrophy of the thymus which most interested the surgeon, since those individuals who died suddenly and unexpectedly usually had an enlarged thymus. There certainly existed strange relationships between the pituitary body, the thymus, the thyroid, the coccygeal body, the testes, the ovaries, and perhaps the bone marrow. In this list the quite recent researches relative to the parathyroids should also be included. A clearer recognition of the function of the latter seemed to have changed the whole aspect in which we should regard Graves' disease, it being made quite probable that this condition was due rather to atrophy of the parathyroids than to excess of the thyroid or its secretion. In the ordinary forms of cystic goiter, where thyroid secretion was not augmented, the symptoms of Graves' disease were lacking. It was usually after removal of the thyroid proper that the opposite symptoms of Graves' disease appeared—*i.e.*, myxedema and cachexia, while when the parathyroids were taken away the peculiar symptoms of Graves' disease appeared. The life-history of the thymus was closely related to that of the testes. Atrophy of the former would seem to depend upon complete maturation of the latter. These statements could be corroborated by a study of cryptorchids and castrated animals. The status lymphaticus was also described under the terms lymphatism, lymphatic constitution, and status thymicus, the condition having apparently more to do with the thymus than any other isolated organ. Thymus extract produced in animals a fall of blood pressure with acceleration of the heart, and, in fatal doses, collapse. Thymic enlargement might cause death by pressure on important structures, even distinct from the trachea. Thymic asthma, a condition known for some time, was one in which death sometimes occurred most unexpectedly and quickly. In these cases not only was the thymus enlarged, but there was found a general hyperplasia of the lymphatic tissue, with enlargement of the lymph nodes and of the spleen. The relations between status lymphaticus and rickets were frequent and pronounced. Nearly all cases of the former displayed the ordinary clinical evidences of the latter. The participation of the lymphatic system was most casually apparent in the involvement of the faucial, laryngeal, and lingual tonsils, *i.e.*, the so-called adenoids of the throat specialists. It was notable that it was in these cases that death most often occurred during or after anesthesia. Thymic asthma was practically the same thing as laryngismus stridulus. The occurrence of this in children ought always to serve as a warning, as well as an indication for careful study and treatment. Should, then, chloroform be given in such a case inadvertently or unnecessarily, the agent would not be nearly as responsible for the death as the practitioner who employed it. The condition was to be recognized by the ordinary evidences of rickets which were usually present, by generalized enlargement of the lymph nodes, the presence of adenoids in the nasopharynx, a history of laryngismus stridulus or special liability to spasm of the glottis, perceptible enlargement of the thymus or notable enlargement of the thyroid or spleen. In the young these conditions simulated cretinism. Such a clinical picture as would afford the above features should serve as a warning and make one abstain from the use of anesthetics unless absolutely necessary, while it should also prompt carefully directed treatment. This treatment should consist in careful attention to elimination, as well as to nutrition, while thymus or pituitary extract should be administered internally, as well as the glycerophosphates or some similar upbuilding tonic. If, now, it should be necessary to clear out the nasopharynx in such a case, the parts should be first desensitized by cocaine, to which a little adrenalin might be added, even previous to beginning anesthesia. If the patient were known to be subject to glottic spasm, one should be prepared to do a tracheotomy on an instant's notice, and especially so if the thymus were perceptibly enlarged. One might even have to use a long trachea tube. Operations of convenience should be postponed until the patients could be carefully built up. Operations of necessity might be practised with the above precautions, while in cases of impending or actual emergency one might depend upon artificial respiration after tracheotomy and the use of adrenalin.

**Patent Urachus, with a Review of the Cases Reported; Operation on a Case Complicated with Stone in the Kidney.**—Dr. George Tully Vaughan of Washington, D. C., explained the defective development in embryology which leads to the formation of patent urachus and of Meckel's diverticulum. He gave a short review of the literature, and stated that the older anatomists held different opinions as to whether the urachus was a tube or a solid cord. He divided cases of patent urachus into the complete, blind, blind internal, and blind external, and into congenital and acquired varieties, and explained the occurrence of some cases of acquired patent urachus by the pressure of urine in the bladder from obstruction to its normal outflow, causing Wutz's valve (a small valve which guards the bladder opening of the urachus) to give way and permit urine to enter the urachus, when, if infection took place, abscess formed, and pus broke through the umbilicus or discharged into the bladder. He briefly recounted 52 cases reported in the literature, and added one case of his own, of which 38 cases were operated on, with 32 recoveries, 3 deaths, and in three the result was not reported. He divided the methods which had been tried for closing the open urachus into 8 classes as follows: (1) The application of caustic or of the actual cautery to the umbilical opening. (2) The use of the cautery and of ligatures or sutures. (3) The use of ligature or suture only. (4) Plastic operations, the application of a flap of skin to close the opening. (5) To open or slit up the urachus, curette or cauterize, and pack. (6) Removal of sources of irritation from the urachus, such as stones, pus, etc., and keeping the parts clean. (7) Removal of obstruction to the flow of urine from the bladder through the urethra, as a tight prepuce, strictures of the urethra, hypertrophy of the prostate, and tumors or stone in the bladder. (8) Extirpation or dissecting out of the urachus and sewing or ligating the part next to the bladder, after the manner of treating the appendix in appendectomy. The author did not approve of the method of simply closing the umbilical end of the fistula, lest an infected suppurating area be left which might cause septicemia or peritonitis. He considered slitting open and packing the abscess cavity a rational operation, but thought the operation of election was to dissect out the urachus with the entire diseased area. Dr. Vaughan used this method in his case—a man of 40, who had an acquired patent urachus since the age of 17. A month after the patent urachus had been cured it was necessary to perform nephrolithotomy on the right kidney, and nine months later the same operation on the left kidney. A brief consideration was given to tumors and cysts of the urachus.

**A Summary of All the Cases of Fracture of the Spine (244) Which Were Treated at the Boston City Hospital from 1864 to 1905.**—Dr. H. L. Burrell of Boston contributed a paper on this subject, in which the author presented the following conclusions: (1) That fractures of the spine may well be divided into two classes—*first*, fractures of the spine with injury to the cord; and, *second*,

fractures of the spine without injury to the cord. (2) That it is not best to decide what the treatment of an individual case of fracture of the spine should be from the statistics, because the lesion varies so widely. (3) That in many cases of fracture of the spine it is impossible to state primarily whether the cord is crushed or pressed upon by bone, blood, or exudate, except by an open operation. (4) That only by the persistence of total loss of reflexes, complete insensibility to touch and pain, and motor paralysis below the level of the lesion can total transverse destruction of the cord be diagnosed. (5) That if pressure on the cord is allowed to remain for many hours, irreparable damage to the cord may take place. (6) That unless it is perfectly clear that the cord is irremediably damaged, an open operation to establish the condition of the cord and to relieve pressure is imperative as soon as surgical shock has been recovered from. (7) That in certain cases of fracture of the spine, when the cord is not injured, but is liable to injury from displacement of the fragments of a vertebra, rectification of the deformity and fixation of the spine may be used. (8) That if the cord is crushed, no matter what treatment is adopted, there will of necessity be a high rate of mortality.

**Case of Suture of the Spinal Cord Following a Gunshot Injury Involving Complete Severance of the Structure.**—Dr. George Ryerson Fowler of Brooklyn, N. Y., reported the case of A. E., aged 18, clerk, born in America, single. The patient was admitted to the Brooklyn Hospital on April 28, 1903. He gave the following history: He suffered from pneumonia several years ago. Four years ago, while working at a machine, his left hand was caught in the latter and so badly crushed that it became necessary to amputate four fingers. He had gonorrhea six months ago; no discharge at the present time. Shortly before admission he was shot in the back, his assailant using a 38-caliber revolver, at a distance of about thirty feet. The shooting took place somewhat from the right side. He suffered severely from shock, and paralysis of the lower extremities occurred at once. The bullet wound was located one and a quarter inches to the right of the medium line and on a level between the tenth and eleventh dorsal spines. He was found to be paralyzed below the waist; sensation was absent over all of both lower extremities, and over the abdomen as high as one inch above the crests of the ilia on the sides, and about halfway between the symphysis and the umbilicus in front. Bladder and rectum were also paralyzed. The bowels moved involuntarily and irregularly, and without the volition or cognizance of the patient. There was considerable twitching of the muscles of both legs, especially the toes. Operation was performed May 9, 1903. An incision was made, six inches long, over the spines of the vertebræ, the middle of the incision resting upon the eleventh dorsal spine. The laminæ of the tenth, eleventh and twelfth vertebræ were removed by the chisel. The bullet was found lying transversely between the severed ends of the cord, concealed from view by a large blood clot. A very narrow, ragged, and contused strip of dura, scarcely more than one-sixteenth of an inch in width, remained intact. The blood clot was carefully sponged away and the bullet removed. The ends of the cord were then sutured with three fine chromicized catgut sutures, the dura being included in the sutures. No special difficulty was experienced in drawing together the ends of the cord and closing the defect, the latter representing in width the diameter of the 38-caliber bullet. The dura was further secured with a number of sutures of fine catgut, and a drain consisting of a half dozen narrow strips of oiled silk protective introduced. The skin incision was sutured with silkworm gut. On May 30 the following note appeared on the hospital record: "Wound healed, upper line of anesthetic area from one and a half to three inches lower than before operation. Twitching of toes of both feet and occasional clonic muscular spasms of the flexors and extensors of the thighs; the patient says his 'feet jump up on him.' Can feel when the bowels move, but is without control of the rectum. Can feel distention of the bladder with urine, but is without control." The main points of interest in this case related to the possibility of regeneration of the spinal cord following a destructive lesion. Prior to the report of Dr. F. F. Stewart's case, in which Dr. R. H. Harte sutured the cord after it was severed by a bullet, it was the opinion of the majority of investigators that such regeneration in man was impossible. Mikulicz, of Breslau, endeavored to demonstrate the possibility of a successful regenerative process in the lower animals following section of the cord, but without result. Spiller and Frazier found that after division of a posterior root in the dog, followed by immediate suture, regeneration occurred, and that regeneration into the cord did not occur. In Dr. Fowler's case, twenty-six months after the injury, voluntary motion was practically lost in the affected area. The patient was able to stand when supporting himself by the hands resting upon an apparatus, and to make some locomotion by swinging movements in a special frame on wheels. The bladder and rectum control was doubtful, to say the least, the former acting automatically. The patient had the sensation that the bladder and rectum were about to empty themselves, and if the urinal or bedpan were brought to him promptly, soiling was prevented. The amount of urine passed in this manner probably averaged more than a pint in the twenty-four hours. The urine was sometimes voided during sleep. Sensation was practically abolished in the entire affected region, with the exception of an area about five inches in length extending down the outer side of the right thigh, where some sensation was present. He was not able to distinguish correctly between heat and cold. Tactile sensations were recognized, but were usually referred to a point two or three inches distant from the point touched. Marked rigidity and spasticity of both legs were present. Patellar reflex exaggerated; Achilles reflex marked; ankle clonus present on one side and absent on the other. The reaction of degeneration was absent. Bed sores developed in the third month; these extended to the muscles and were six months in healing. The skin showed but slight, if any, evidences of trophic disturbance. A final and important comment was suggested in comparing this case with the Stewart-Harte case, namely: The Stewart-Harte case was operated on three hours after the injury, while in Dr. Fowler's case upwards of ten days had elapsed before consent to interfere operatively was obtained. The prolonged separation of the divided ends of the cord and the presence of the foreign body had, in all probability, an influence in preventing a complete regeneration of the cord, as occurred in the first case, provided, of course, that regeneration did actually occur. While the case in hand was therefore not so striking in many of its features as the Stewart-Harte case, the author thought it presented some points of interest, and for this reason was offered as a contribution to the literature of the subject.

**The Surgical Treatment of Intraspinal Tumors.**—Dr. Richard H. Harte of Philadelphia said that the science of spinal localization was now so well developed that it usually was not difficult to determine with accuracy the location of an intraspinal growth. What was usually understood by the term tumor of the spinal cord was an extramedullary but intraspinal growth like a sarcoma, a fibroma, or a myxoma, giving no evidence of its existence except by the symptoms of medullary pressure which it produced. There had been found records of 92 operations for spinal tumors, among which number 43 patients died, a total mortality of nearly 47 per cent. The nature of the tumor was recorded in 88 of the reported cases. It was sarcomatous in two-fifths of the whole number (37 cases); adhesions, thickenings, etc., hold second place, with 11 cases; then came echinococcus, 8 cases; fibroma, 6 cases; syringomyelia, 5 cases; endothelioma, 4 cases; psammona, 3 cases; cyst, 3 cases; fibromyxoma, 2 cases; osteoma, 2 cases, and one each of myeloma, lipoma, lymphangioma, dermoid cyst, primary and secondary carcinoma, and one

tumor of bone whose nature was not stated. The author reported an interesting case of paraplegia from Pott's disease in which he resorted to laminectomy, with great improvement. With very few exceptions, he said, it was impossible to determine the nature of the tumor before operation. He reported a case of dermoid cyst of the spinal canal on which he operated, followed by recovery, the patient being a girl 7 years of age. Of 82 cases in which the region of the spine affected was given, the upper dorsal region was involved in 33 cases, or over 40 per cent. The tumor was found in the lower dorsal region in 24 cases, in the lumbosacral region in 14, and in the cervical region in 11 cases. The cause of death was given in 28 cases. One-half of these were due to shock and hemorrhage, or to infection and meningitis, there being seven fatal cases under each of these categories. Eight patients died from exhaustion, three from recurrence of malignant growths, two from hypostatic pneumonia, and one from bed sores and sepsis. As regards the technique of the operation, it was essentially the same as when employed in traumatic cases.

### SECTION ON DISEASES OF CHILDREN.

*Third Day—Thursday, July 13.*

**Ataxia of Central Origin in Childhood.**—Dr. ARTHUR WILLARD FAIRBANKS of Boston read this paper which was a consideration of a symptom-complex, the most characteristic features of which are muscular incoordination of the extremities and of the trunk, head, larynx, tongue, and eyes; slowness of muscular action, slow, hesitating speech, sometimes of nasal character and occasionally explosive; swaying; unsteady gait; nystagmus; oscillation or tremor of head, body, or extremities; certain involuntary movements, which may or may not be of choreiform character, and which may occur independently, or may be associated with volitional intended movement of some other part of the body; lateral curvature of the spine; deficient energy in executing voluntary movements; and, in an advanced period of the disease, paralysis, muscular spasm, and contractures. Vertigo; headache; optic atrophy; and impairment of action of pupils and of the external ocular muscles; apathy of facial expression; loss of muscular tone; involuntary, unprovoked laughter; sensory disturbances; peculiar deformity of the feet; disturbance in action of the sphincters; muscular atrophy and minor trophic changes in the skin; are to be considered inherent but less common phenomena. Certain other symptoms, such as depreciation of intellectual power, psychical phenomena, epileptic attacks, etc., were mentioned as complicating phenomena due to implication of other parts of the nervous structure than that usually affected by the disease. In the class of cases covered by this symptom-complex, Dr. Fairbanks remarked that there should be probably included cases previously described under the title of Friedreich's disease, cerebellar ataxia, or hereditary ataxia. In his opinion, careful study of a large number of cases indicates that it is impossible to establish any arbitrary differentiation between the varying types reported, these cases merging into one another in such a manner that it is clearly evident that it is a question of extent, duration, and location of the process rather than a matter of difference in nature. This, also, pathological demonstration sufficiently proves. The varying condition of the knee jerks, so long a bone of contention between the adherents for and against the maintenance of Friedreich's original type, in the writer's opinion, is of no differential diagnostic value, but only indicates whether or not the process has involved certain definite portions of the nervous structure. Several cases have come under the observation of the writer, in the early stage, in children from three to ten years of age. In none of these children were the knee jerks absent. The clinical features in these cases were the unsteady "cerebellar"-gait, well marked ataxia of the extremities, especially the upper; and, in some of the cases, affection of speech, choreiform movements and nystagmus. That many of the symptoms of the complex suggest cerebellar affection, the writer stated was evident, and it was found that post-mortem examination of the very pronounced cases of Menzel, Nonne, and Sanger Brown showed, in addition to the degenerations in the posterior columns, the direct cerebellar tracts, Clarke's columns, and the posterior nerve roots in the cord, marked changes in the cerebellum, pons, and medulla were present. Certain features of the complex have also been features of experimental lesions in animals as well as affections of the cerebellum in human beings.

Dr. WAHRER asked whether there were degenerative nutritive changes in the nerves.

Dr. H. E. GARRISON inquired whether there had been any tuberculous tendency present, and cited a case in which there was almost complete paralysis.

Dr. Fairbanks replied that there was extreme atrophy of some of the nerves, and to Dr. Garrison that there was no ground for the assumption that tuberculosis was an element in the etiology or pathology, but that tuberculous processes were sometimes the terminal features of the disease.

**Pneumonia in the Young.**—Dr. EDWARD F. WELLS of Chicago said that to estimate fairly the prevalence and fatality of pneumonia in the young was a statistical and judicial feat of no mean proportions. From an analysis of 30 025 cases of and 225,642 deaths from pneumonia, he concluded that during childhood pneumonia is encountered oftener than at any other period; from 10 to 30 years much less frequently; from 30 to 50 somewhat oftener. On the contrary, if its prevalence is estimated by comparing the deaths caused by pneumonia with the number of persons living at various age periods, it will be found that in early childhood its mortality prevalence is moderate; from 10 to 20 years it sinks to its lowest level; from 20 to 50 it gradually but markedly advances; it is greatest in old age. These facts were clearly shown in an accompanying table and curves. The recently born infant is the least likely to be affected by pneumonia. The physical signs of pneumonia are present and discoverable at some stage in practically all cases. The course, type, severity, and danger of an attack of infantile pneumonia, he said, will vary in different localities and at various times, depending upon the natural or acquired virulency of the strain of infecting pneumococcus. He had found empyema the chief of the serious complications, and these are found more frequently in the pneumonia of the young than of adults. In the presence of doubt, he would use the exploring exhaust needle without the slightest hesitation. The majority of cases of alleged "unresolved pneumonias" in children were in fact examples of empyema Otitis media he had encountered rather frequently. The morbid anatomy of pneumonia in early life, he said, is modified by the structure and functional peculiarities appertaining to this period. Prognostically pneumonia in the young is at present an unsolved problem. The application of the underlying principles of proper management to meet the exigencies of the individual patient is an art which the author believes cannot be transferred from one physician to another. Eminence in this art is attained only by those who have extraordinary natural capacity, a broad foundation, and keen perception of the pertinent facts with the advantage of long years of practice. He favored the giving of liquids as freely as they could be taken The child should be disturbed as little as possible, the purest, freshest, and most

comfortable air should be supplied. Beginning early, it was his practice to give moderate or large doses of a reliable tincture of digitalis; various other vasomotor stimulants might be used. Oxygen inhalations were useful when the patient was not fretted by their use. He would also make use of decinormal salt solutions

Dr. A. C. COTTON endorsed the speaker's therapy along the line of supplying salines. He thought it important to maintain the alkalinity of body fluids, especially in a disease like pneumonia with high temperature and intoxication.

Dr. W. J. BUTLER of Chicago thought the diagnosis of lobar pneumonia in infancy not so difficult as was usually supposed He considered the clinical picture quite as typical as in the adult, as are also the physical signs. The diminished respiratory murmur, sometimes almost complete absence of it, with diminished resonance he has found the most conspicuous sign of beginning pneumonia in children under two and a half years. He does not think that there should be associated rigidity of the neck with middle ear disease in pneumonia, because in pneumonias during certain epidemics meningeal symptoms will sometimes predominate the whole clinical picture, and because middle ear disease may occur with any infection of the respiratory tract or of the throat, and in those cases rigidity of the neck is rather the exception. Therefore, he would style those symptoms usually as pseudomeningeal symptoms.

Dr. T. L. RILEY of New York said that with the stethoscope modeled on the plans of the phonendoscope one could hear twenty-four hours earlier in the many so-called central pneumonias than with the ordinary form of stethoscope. Lobar pneumonia in children, in his experience, is one of the safest diseases the physician is called to see. He considered the mortality to be about three or four per cent. The old-fashioned poultices appear to give more comfort to children and old people than the anodynes. The physician who loses the greatest number of cases is the one who sees his patients the least often.

Dr. FAIRBANKS asked to what Dr. Wells attributed the extreme fetor sometimes seen in these cases.

Dr. JOHN LOVETT MORSE called attention to the importance of differentiating the pneumonia of infants and the pneumonia of children; in the former it was extremely fatal; in the latter an extremely mild disease. In his opinion, the most important point in diagnosis of pneumonia in infancy was the increase of respiration out of proportion to the pulse rate. This in an acute disease with a high temperature in an infant almost certainly means the presence of pneumonia. In his experience children with otitis media complicating pneumonia do not show symptoms pointing directly to the ear. Another noticeable point is the frequency with which the symptoms of pneumonia are referred by the child to a point away from the lung. With an abundance of fresh air he would not consider oxygen an essential, and he would not use poultices except for the relief of pain.

Dr. A. C. COTTON advocated the abstraction of bloody by leeching for the relief of the right heart in pneumonia.

Dr. Wells in closing said that increasing the alkalinity of the blood in pneumonia might be useful, detrimental, or innocuous. He believed the work along this line to be in the early stages of investigation and without sufficient facts to determine its value. He had intentionally omitted mention of methods of treatment which are in the investigational period. He believed that inferentially the introduction of large quantities of sodium chloride in the system might be considered useful. This method, however, is also in the investigational period. One of the first and most important symptoms of pneumonia, he observed, was the decline, almost the absence, of chlorides in the urine. Personally he was in the habit of giving chlorides as freely as possible, but did not advocate the intravenous injection. He particularly emphasized the value of an abundance of comfortable pure air. He believed there were no facts to warrant the belief that uncomfortable air—overheated or overcooled—was more beneficial to the patient. In regard to the fetor of the breath, he thought there was not sufficient evidence for an opinion. In some cases this was due to the fact that the child did not breathe through the nostrils; the mouth remained open and the secretions in the throat and nose became fetid. Rigidity of the neck, in his experience, had been found most frequently in connection with otitis media. He believed that Dr. Riley's estimate of mortality was too low.

**Pleural Effusions in Children.**—Dr. C. F. WAHRER of Fort Madison said that the object of his paper was to bring out discussion which would throw light upon the diagnosis of pleural effusions. He thought the condition was often overlooked, and when recognized frequently not treated with sufficient vigor. Nine-tenths of the cases in children he believed follow pneumonia or broncho- or pleuropneumonia. Tuberculosis is too often considered a causative factor. A pleural cavity, properly speaking, he stated, only exists when the layers of the pleura are distended with fluid. The diagnosis of the effusions he regarded as more difficult than ordinarily supposed. Auscultation, palpation, and percussion he regarded as usually sufficient, and when in doubt he would aspirate. In aspiration the anatomy of the parts must be borne in mind. The prognosis he regarded as dependent upon early diagnosis, faithful treatment, and the progress of the disease causing the effusion. In general the prognosis is better in children than in adults. When the disease is purulent, surgical treatment is always indicated The choice of methods was described. He regards the operation as simple and has found the results usually good.

Dr. COTTON referred to the suggestion of Holt to locate the apex beat if possible in every case of suspected empyema where the needle shows pus.

Dr. W. J. BUTLER was inclined to regard with great skepticism the diagnosis of pleural effusion necessitating surgical interference when the dullness was obscured by a change of position of the patient. The absence of fremitus would be a more valuable diagnostic sign than the presence of bronchial breathing. He thinks it desirable to wait for a little while to see what the case is going to do before puncturing.

Dr. D. S. HANSON of Cleveland thought that the diagnosis of pleural effusions could be made without the needle.

Dr. Wahrer in closing repeated his statement that some of the cases are unrelieved and end in death for want of diagnosis and proper treatment. He felt that there was no harm in introducing the needle into the chest if the chest, hands, and instrument were pedantically clean.

**Typhoid Fever in Children.**—Dr. WILLIAM J. BUTLER of Chicago reviewed the literature of the subject and remarked that Hippocrates' description of a fever observed by him during autumns would form an excellent picture of what is now termed typhoid fever. Dr. Butler regarded it quite impractical to make an accurate estimate of the frequency of typhoid in children without reference to statistics derived in epidemics taking place in small towns. A table of statistics of this character was given. The clinical analysis of 210 cases, including symptomatology, blood examinations, relapses, complications, mortality, and treatment was also given. The children presented symptoms for from a few to ten days before coming under observation. These symptoms were detailed in the paper, as were those observed during the course of the disease. Anorexia was invariably present. Vomiting occurred in 28 cases during the course of the disease; in 13 of these it had been present at the onset. Roseola were found in many cases but seldom before the sixth day of the disease. While the respiratory rate was usually somewhat increased, as a rule it was not accelerated beyond its normal ratio to the pulse rate, unless pulmonic complications developed. Eighty-two of the

210 cases ran a high temperature lasting from 18 to 55 days; 90 had an elevated temperature for less than 15 days. A table showing the average duration of the disease for each year of age was shown in the paper. The disproportion between the pulse rate and temperature observed in adults, the author stated, holds good for later childhood, but in very young children the pulse runs more or less parallel with the temperature. Blood counts were made in many cases and the weekly average counts of leucocytes were shown in tabulation. Eighty-six cases gave positive Widal reaction; 10 negative. Headache was almost a constant symptom among the older children for the first week or two. Relapse, in the writer's opinion, seems more frequent in children than in adults. The mortality of typhoid fever in children he regarded considerably lower than in adolescence and later life. Many of the cases under observation presented interesting disturbances of the nervous system; in a boy of 11 years, the left eye was noticed to be turned in on the second day. Three cases showed more or less marked meningeal symptoms. There was acute angina in five cases. Six patients developed pneumonia. The treatment employed consisted in proper hygiene, appropriate diet, and symptomatic treatment, including hydrotherapy; in some instances intestinal antisepsis, and the treatment of special symptoms and complications as they arose.

Dr. Quevil of Tacoma asked if the author would speak upon the differential diagnosis of typhoid fever and tuberculosis in children.

Dr. Fairbanks said that he had been interested in noticing the fact that in children the rule of differential diagnosis of typhoid fever and tuberculosis—the disproportion between heart and temperature—does not apply. He referred also to the value of the leucocyte count in diagnosis.

Dr. Butler in closing referred to a case mentioned by Dr. Cook in his paper in a series of enterocolitis which illustrated that in typhoid fever in infancy, under two years, the only sure and positive way of diagnosing was by the Widal reaction.

Dr. Wahrer asked what were the results with the dry specimen test, and Dr. Butler replied that the test was quite as satisfactory as with the fresh serum.

**The After Effects of Diphtheria Upon the Heart.**—Dr. Franklin W. White of Boston presented the above paper, which was read by the Secretary. In a study of the heart complications in nearly 1,000 cases of diphtheria treated at the South Department of the Boston City Hospital, it was found that while severe heart complications are relatively infrequent, moderate disturbances of the heart are very common. The large number of children discharged from the hospital with a rather rapid and irregular pulse and cardiac murmur contrasted strongly with the condition of children at the end of other acute infections. The paper was a statistical study of 78 cases of diphtheria with heart complications after discharge from the hospital. Sixty-five cases to all appearances became entirely well. Especial care was urged in examining the hearts of children, because in health the physical signs vary with the age of the child and because in heart disease the signs are not the same as in adults. An important physical sign present was cardiac enlargement accompanied by a systolic murmur at the mitral area and an accentuated pulmonic second sound. Histories were given of a number of cases of the average type, also of the severe type.

The following were the conclusions: (1) The cardiac disturbance after diphtheria usually presents the picture of a mitral insufficiency with regular heart action and few symptoms. Occasionally cases have rapid pulse or cardiac irregularity without any other signs. (2) Moderate disturbance of the heart is very common after diphtheria, and in a large number of cases persists for from two to six months after the original illness. (3) In many cases the cardiac lesion does not clear up in the first half year; some ultimately recover; others probably do not. The duration of the heart trouble is usually in proportion to the severity of the original illness. (4) The fact that children often have few heart symptoms after diphtheria must not mislead us as to the importance of injury to the heart. (5) Cardiac disturbance of long duration following diphtheria may be entirely recovered from. (6) The treatment of the condition consists in a sufficient period of rest in bed and then in watching the effects of mild exercise upon the heart for several months and grading it to meet the individual requirements.

Dr. G. R. Campbell of Augusta strongly endorsed the value of rest after diphtheria as a preventive treatment of the after effects of the disease upon the heart. He thought many physicians were apt to feel that their cases of diphtheria were entirely well as soon as the throat was cleared and the patient able to sit up. He felt that the action of the heart after moderate exercise should be the warning note that the heart muscle had not resumed its normal tone.

Dr. H. M. McClanahan of Omaha referred to the feeling among the laity, and entertained, perhaps, by some members of the medical profession, that antitoxin in the treatment of diphtheria was injurious to the heart. He attaches much importance to the time of its administration. He agreed that the child should be kept in bed until the pulse has resumed its normal rate.

Dr. Butler of Chicago thought the time of the administration of the antitoxin in relation to the onset of the diphtheria was of much importance. The cases receiving the treatment within the first forty-eight hours, he thought seldom showed deleterious after-effects upon the heart. He thought Dr. White had somewhat overrated the value of the systolic murmur as indicative of mitral insufficiency, and thought that in almost any of the acute infections there might be systolic murmurs without organic lesion. The irregularity both in quality and rhythm he thought the most important points with reference to the deleterious effects of the diphtheria toxins upon the heart.

Dr. Fairbanks thought that without doubt the cases of heart lesion following diphtheria have seemed to increase since the use of antitoxin. The chief factor in this he thought was that the majority of patients with very severe diphtheria now recovered while formerly the majority died during the diphtheria. He thought Dr. Campbell's warning against allowing the children to get up too soon was of much importance, and that the fault was not with the parents alone, but with the family physician. On account of the quarantine rules, some of the children are kept in a room for a good many days, which results fortunately for the child. During the acute stage he does not think that the occurrence of systole can be interpreted as an indication of mitral insufficiency. Later on it is an index of insufficiency, although that insufficiency may be only a relative one. He thought that in this country the Schott treatment of heart disease was not sufficiently practised.

Dr. Wahrer said that the apparent increase of heart lesions since the introduction of antitoxin was similar to the seeming increased frequency of operations. The explanation lay in the fact that to-day surgery is saving the very people who were formerly allowed to perish.

Dr. H. E. Garrison referred to the diet in diphtheria and cited a case in which death had occurred from indiscretion in eating.

Dr. Lindsay emphasized the remarks in regard to the necessity of careful diet until after the subsidence of the disease and thought physicians should aim to be specialists in giving directions for the care of the sick as well as specialists in other departments of medical science. Not only should a child be kept physically quiet but also free from nervous excitement.

Dr. William J. Butler of Chicago thought the presence

of a systolic murmur following diphtheria could not be accepted as evidence of cardiac disease unless there was a very marked dilatation, especially of the left ventricle.

Dr. John Lovett Morse thought that the statement of Dr. White, in his paper, that functional murmurs of the heart in childhood were rare, was absolutely a misstatement; and that, on the contrary, they were very common. He thought the work of Dr. White important, because it had been carefully done by competent men.

**The Management of Children with Typhoid Fever.**—Dr. W. C. Hollopeter of Philadelphia thought the early diagnosis of typhoid fever was not an easy matter, because the disease is frequently ushered in under the disguise of some other acute disorder. He gave a brief outline of the methods of treatment which he had found most satisfactory. The Widal and Diazo reaction he considered of little value prior to the beginning of the second week. Any treatment that would lessen the toxemia and shorten the leakage in the general circulation he regarded as a step toward a specific treatment. The two essential elements to successful treatment were to reduce the toxemia and supply food and fluid. The first step toward this end was quietude in a large, well ventilated room with the administration of calomel, and a daily colon irrigation. He placed the emphasis of the whole treatment upon the manipulation of the colon washing, which is carried out daily unless there is grave contraindication. The temperature of the irrigation is governed by the temperature of the body. He frequently substitutes bicarbonate of sodium for the chloride or adds tincture of asafetida or some aromatic infusion if tympanites and pain are troublesome.

Dr. John C. Cook of Chicago accentuated the value of water in treatment.

Dr. Lindsay used the ice-bag to advantage in typhoid fever with the application for three to five minutes of warm fomentations immediately following.

Dr. A. C. Cotton thought there was too great a tendency to trust the details of colon irrigation to the nurse, and too often the rectal tube would be introduced with the child lying on its back, in which position there was danger of traumatism to the posterior wall of the rectum.

Dr. Morse urged care in the formation of a too favorable opinion of the results of the treatment of water internally. Since the vasomotor system is relaxed and all the blood vessels, care must be exercised about further dilating the vessels. Personally he did not keep patients with typhoid fever on so restricted a diet as is usually done, and did not believe that a diet entirely of milk was the best one. Diluted cream gives a greater calorie value th n milk and without much residue.

Dr. Hollopeter in closing said, with reference to possible injury to the bowel in colon irrigation, that he never allowed the tube to be inserted beyond the sphincter until the water was turned on. This gave a water cushion to dilate the bowel slowly and the tube following was not liable to cause injury.

**Report of a Case of Imperforate Rectum with Absence of the Anus.**—Dr. Edward H. Small of Pittsburg reported the case, which was that of a male born under his care. The raphe ran from the base of the scrotum to the tip of the coccyx. There was phimosis and the base of the penis was turned toward the scrotum. When the boy was thirty hours old he was held in the exaggerated lithotomy position and without the use of anesthesia a trocar one-fifth of an inch in diameter and two and one-half inches long was thrust, by Dr. J. A. Hawkins, into the perineum where the anus should have been, and in the direction where the rectum should have been, into the hollow of the sacrum. When the trocar was about all introduced lack of resistance was noticed, the stylet was withdrawn, and meconium came out through the cannula. The opening was further enlarged, and the rectum could be felt at the bottom of the wound. The bowel was not sutured to the external wound owing to its firm attachment. A rubber catheter was inserted and secured. In five hours the baby was resting quietly and the subsequent course was favorable. At twenty months old the mother reports that the bowel movements are the same as those of other children of the same age. The anus is somewhat funnel shaped, the sphincter is in good working order, but is about one-half inch higher than normal. The dilators are used once a month but cause no pain. The author stated that the case belongs to the third species of Bodenhammer's classification of the Congenital Malformations of the Rectum and Anus.

**Officers.**—The following officers of the Section were elected: *Chairman*, Dr. W. C. Hollopeter of Philadelphia; *Secretary*, Dr. William J. Butler of Chicago; *Member of the House of Delegates*, Dr. C. F. Wahrer of Fort Madison.

Dr. J. Ross Snyder offered the following resolution, which was seconded and carried: "Resolved by the Section on the Diseases of Children of the American Medical Association that the Chairman appoint a committee of three to ascertain the average number of hours and the relative importance given to the subject of pediatrics in the medical schools of the country; to investigate the various methods and the efficiency of the instruction in this subject; and that this committee shall make a report to this body at its next annual meeting."

The Chair announced that he would make the appointments later. The section then adjourned.

---

**A Case of Vision Acquired in Adult Life.**—James Burt Miner has had the opportunity of studying a case of complete congenital cataracts in which vision was not acquired until adult life. The patient in question was blind from birth. She was operated on when she was twenty-two years of age. The results of the observations which have been made on this patient up to the present time are presented by the author as follows: While hearing and touch show great keenness in some respects, there seem to be no records that cannot be explained on the basis of greater interest and training, and without supposing a compensatory change in the capacity of these sense organs. Color vision is so far above normal as to contradict any supposition that twenty-two years of disuse would cause degeneracy. On the contrary, the color process deteriorates with either use or the removal of the lens and unusual interest produces a remarkable ability to discriminate colors. A very surprising fact is that the patient sees black objects larger than white objects of the same size. This reversal of irradiation indicates that a central process may readily outweigh the retinal process. The absence of retinal rivalry suggests that this process is developed by education; and the tendency to regard a single object as double indicates that this is the nature of the first visual experience with two eyes. Contrary to a prevalent opinion, single binocular vision may be acquired, at least temporarily, by an adult born blind. In regard to the experiments to determine the patient's conceptions of form, solidity, distance, and number, it was noted that number and space perceptions were apparently dependent upon movement. The writer believes that on account of the irresistible impulse to move and to touch, it may be doubted whether a blind person who acquires vision is a suitable subject to decide whether visual images have spatial meaning apart from movement. An unexpected spread of training, especially in memorizing the visual impressions of printed letters and sentences, suggests a caution as to the amount of training which an intelligent adult may transfer from one field to another. The preliminary tests which the writer has been able to carry out indicate that there are only slight differences between auditory touch and visual memory of a series of letters or of sentences.—*The Psychological Review.*

**A Rapid Staining Method for Microscopic Sections.**—Wederhake recommends the following process for use in making diagnoses from frozen sections. After the frozen section has been made in the usual manner, it is placed directly in a freshly prepared diluted iodine solution consisting of two to five drops of the tincture of iodine in 20 c.c. of water. It is allowed to remain in this one to five minutes, and then, without washing, it is carried into the staining fluid. The stock solution for this is a saturated solution in 70 per cent. alcohol of crocein-scarlet, and for ordinary sections 20 c.c. of this are added to 100 c.c. of water. The section is kept in this stain for from one-half to three minutes, and is then mounted in glycerine. Fixed sections and urinary sediments can be stained in the same way.—*Zentralblatt f. Gynäkologie.*

## Books Received.

*While the* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

PSYCHIATRY. A TEXT-BOOK FOR STUDENTS AND PHYSICIANS. By STEWART PATON, M.D. 8vo, 618 pages, illustrated, muslin. J. B. Lippincott Company, Philadelphia. Price, $4.00.

TREATISE ON ORTHOPEDIC SURGERY. By EDWARD H. BRADFORD, M.D., and ROBERT W. LOVETT, M.D. Third Edition. 8vo, 669 pages, illustrated, muslin. William Wood & Company, New York. Price, $5.00 net.

THE SURGICAL ASSISTANT. A MANUAL FOR STUDENTS, PRACTITIONERS, HOSPITAL INTERNES, AND NURSES. By WALTER M. BRICKNER, B.S., M.D. 8vo, 363 pages, illustrated, muslin. International Journal of Surgery Co., New York. Price, $2.00 net.

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY, SIXTEENTH SESSION. Held at Detroit, Mich., May 30, 31, and June 1, 1904. Edited by Linnaeus Edford La Fetra, M.D. Vol. XVI. 8vo, 296 pages, illustrated, muslin.

FOURTH ANNUAL REPORT OF THE METROPOLITAN WATER AND SEWER BOARD. January 1, 1905. 8vo, 277 pages, illustrated, muslin.

A MANUAL OF ACUTE POISONING WITH METHODS FOR USE IN FIRST AID TO THE INJURED. By JOHN W. WAINWRIGHT, M.D. 16mo, 96 pages, muslin, flexible. E. R. Pelton, New York. Price, $0.75 net.

FIRST AID IN ILLNESS AND INJURY. By JAMES EVELYN PILCHER, M.D., L.H.D. Ninth Edition. 16mo, 356 pages, illustrated, leather. Charles Scribner's Sons, New York.

DIETETICS FOR NURSES. By JULIUS FRIEDENWALD, M.D., and JOHN RUHRÄH, M.D. 8vo, 363 pages, illustrated, muslin. W. B. Saunders & Co., Philadelphia. Price, $1.50 net.

THE TREATMENT OF FRACTURES, WITH NOTES UPON A FEW COMMON DISLOCATIONS. By CHARLES LOCKE SCUDDER, M.D. Fifth Edition. 8vo, 563 pages, illustrated, muslin. W. B. Saunders & Co., Philadelphia. Price, $5.00 net.

HUMAN PHYSIOLOGY. By JOSEPH HOWARD RAYMOND, A.M., M.D. Third Edition. 8vo, 687 pages, illustrated, muslin. W. B. Saunders & Co., Philadelphia. Price, $3.50 net.

DISEASES OF THE KIDNEYS AND OF THE SPLEEN, AND HEMORRHAGIC DISEASES. By DR. H. SENATOR and DR. M. LITTEN. Edited by James B. Herrick, M.D. Authorized translation from the German. 8vo, 815 pages, illustrated, muslin. W. B. Saunders & Co., Philadelphia. Price, $5.00 net.

HAND-BOOK OF ANATOMY; BEING A COMPLETE COMPEND OF ANATOMY, INCLUDING THE ANATOMY OF THE VISCERA AND NUMEROUS TABLES. By JAMES K. YOUNG, M.D. Second Edition. 8vo, 402 pages, illustrated, flexible muslin. F. A. Davis Company, Philadelphia. Price, $1.50 net.

THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA. Eighth Decennial Revision. 8vo, 692 pages, muslin. P. Blakiston's Son & Co., Philadelphia.

REPORT OF THE COMMISSIONER OF EDUCATION FOR THE YEAR 1903. Vol. 2. 8vo, 1217-2511 pages, muslin.

LES CARDIOPATHIES ARTÉRIELLES ET LA CURE D'EVIAN. Par Le Dr. P. BERGOUIGNAN. 8vo, 159 pages, paper. Georges Steinheil, Paris, France.

LA CHIRURGIE ENSEIGNÉE PAR LA STEREOSCOPIE—GUIDE DES OPERATIONS COURANTES. I. CURE RADICALE DE LA HERNIE INGUINALE. 12mo, 28 pages, illustrated. J. B. Baillière et Fils, Paris, France.

BEITRÄGE ZUR KLINIK DER TUBERKULOSE. Herausgegeben von DR. LUDOLPH BRAUER. Band 14. Heft 1. By various authors. 8vo, 112 pages. A. Stuber, Wurzburg, Germany.

A SYLLABUS OF MATERIA MEDICA. Compiled by WARREN COLEMAN, M.D. Second Edition. 32mo, 189 pages, muslin. Wm. Wood & Company, New York. Price, $1.00 net.

OPHTHALMIC NEURO-MYOLOGY. By G. C. SAVAGE, M.D. 8vo, 221 pages, illustrated, muslin. Published by the Author, Nashville, Tenn.

GYNÄKOLOGISCHE DIAGNOSTIK. IN ZWANGLOSEN VORTRAGEN FÜR STUDIERENDE UND ARZTE. Von Dr. MAX HENKEL. 8vo, 256 pages, illustrated. S. Karger, Berlin, Germany.

DIE PALPABLEN GEBILDE DES NORMALEN MENSCHLICHEN KORPERS UND DEREN METHODISCHE PALPATION. Von Dr. TOBY COHN. 1. Teil: Obere Extremitat. 8vo, 216 pages, illustrated. S. Karger, Berlin, Germany.

## Medical Items.

**Contagious Diseases—Weekly Statement.**— Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending July 29, 1905:

| | Cases | Deaths |
|---|---|---|
| Measles | 274 | 13 |
| Diphtheria and Croup | 166 | 13 |
| Scarlet Fever | 54 | 4 |
| Smallpox | ..... | ..... |
| Chickenpox | 14 | ..... |
| Tuberculosis | 342 | 141 |
| Typhoid Fever | 141 | 18 |
| Cerebrospinal Meningitis | 21 | 10 |
| Typhus Fever | ..... | ..... |
| Yellow Fever | ..... | ..... |
| Cholera | ..... | ..... |
| Totals | 1,012 | 199 |

**Health Reports.**—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending July 29, 1905:

SMALLPOX—UNITED STATES.

### A NEW METHOD OF ORCHIDOPEXY.*

By CARL BECK, M.D.,

NEW YORK.

PROFESSOR OF SURGERY IN THE NEW YORK POSTGRADUATE MEDICAL SCHOOL AND HOSPITAL, VISITING SURGEON TO THE ST. MARK'S HOSPITAL AND THE GERMAN POLIKLINIK.

RETENTION of the testicle is a very frequent condition, and deserves much greater attention than it generally receives; its dangers, such as fatty or fibromatous degeneration, as well as its tendency to inflammation, intumescence, and strangulation, being considerably underrated. Its great tendency to malignancy is illustrated by the cases of Kocher, Fischer, Johnson, Spencer Wells, Maydl, von Kahlden, Butjaegin, and Eigenbrodt; and in connection

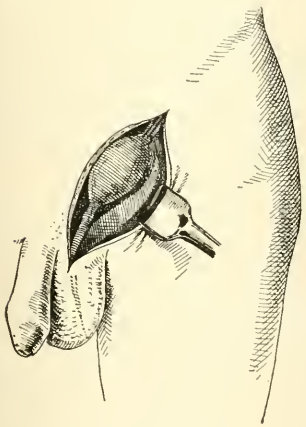

Fig. 1. Formation of flap.

with a case of hermaphroditism I have called attention. As a rule, no operative interference is requested, the frequency of malignancy under these conditions. Fischer bases his views on forty and Kocher on sixteen cases of the inguinal type of retention.

The patients are generally of a nervous disposition. As a rule, no operative interference is requested, because of the widespread and erroneous opinion that the displaced testes will descend at the age of puberty. I will not deny that this may sometimes occur, but I have never observed it myself, nor have any of my surgical friends on whose experience I have called. It seems to me to be unwise, therefore, to defer surgical interference until puberty—that is, until after the testis has become more and more atrophied, and I advise it after the third year, unless there is some strong contraindication.

*Demonstrated before the Surgical Section of the Academy of Medicine, April 21, 1905.

It was Schueller who first advised orchidopexy. His *modus operandi* consisted in first dividing the vaginal process and fixing the undescended testicle in the scrotum by suture. His example was soon

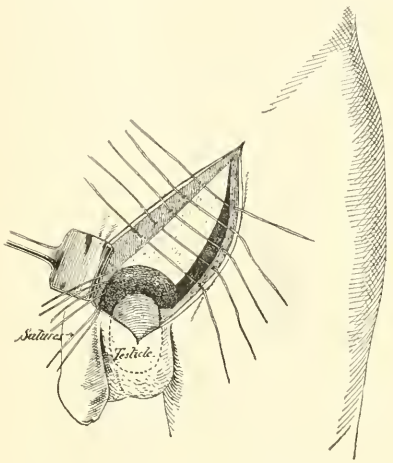

Fig. 2. Testicle held down by inserting flap.

followed by Kocher, Nicoladoni, Tillmanns, and others. In a number of cases the patients improved,

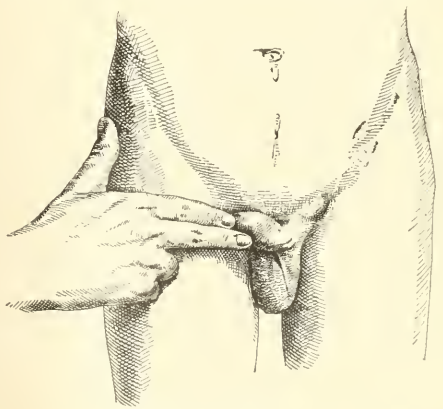

Fig. 3. Scrotum containing the right testicle; the undescended testicle in the left inguinal region.

but in most of them the testis was drawn back again towards its former habitat.

Bevan deserved great credit for calling attention to the main cause of the failures—the insufficient

liberation of the cord from the surrounding tissues. No doubt his ingenious method permits of the most thorough reduction of the testis, avoiding tension at the same time; but this is effected at the expense of the blood-vessels to such an extent that the further nutrition of the testicle is seriously threatened.

The method which I have employed does not interfere with the vessels, and retains the reduced testicle nevertheless. The *modus operandi* is the following: The incision is similar to that of Bassini for the operation for inguinal hernia. It extends from the external ring for more than three inches downward alongside the normal direction of the cord, and divides the aponeurosis of the external oblique, the cremasteric fascia, and the thin transversalis fascia. After the pouch of the testicle is opened, the testicle is lifted from its bed and pulled down, while all the tense bands of connective tissue, as well as the peritoneal adhesions which prevent its mobility, are carefully and thoroughly divided. The testicle being thus well mobilized, a pocket is formed in the scrotum, into which it is pulled down. In order to secure it there, a flap is dissected from the outer margin of the inguinal ring downwards (Fig. 1) and turned in such a manner that it can be

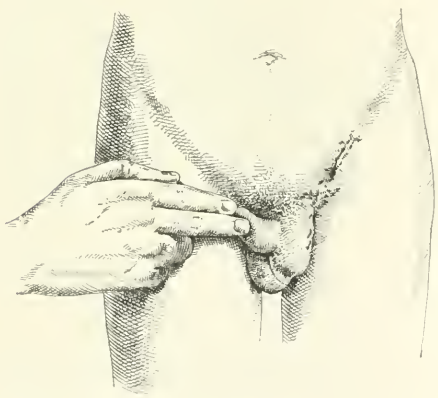

Fig. 4. Left testicle held in scrotum; two weeks after the necktie operation.

attached to the opposite layer in a semilunar shape (Fig. 2). Thus this band surrounds the testicle like a necktie, the testicle being retained as in a buttonhole. The length of the semilunar flap will be determined by the greater or less extensibility of the cord. The aponeurosis is then united above.

It is evident that the defect caused by the displacement of the flap narrows the canal, which is a decided advantage if there happens to be any tendency to hernia.

The patient whom I present to you is a youth of eighteen years, who, as Fig. 3 shows, suffered from the inguinal type of retention of the testis. The "necktie operation" was done without difficulty, and, as can be readily seen, the testis remains at the fundus of the scrotum (Fig. 4). Recovery was uninterrupted.

If the tension on the cord is considerable, as is usually the case, the "necktie" may be attached a little further above. It seems to me of little importance whether the testis finds lodgment further up or down in the scrotal cavity, so long as it actually is placed within the scrotum.

## ASCENDING CURRENTS IN MUCUOUS CANALS AND GLAND DUCTS, AND THEIR INFLUENCE ON INFECTION: A STUDY IN SURGICAL PATHOLOGY.*

By C. J. BOND, F.R.C.S.,
LEICESTER, ENGLAND.
HONORARY SURGEON, LEICESTER INFIRMARY.

I PROPOSE, in using the opportunity now afforded me, to depart somewhat from the usual custom, and instead of adopting a retrospect of recent surgical triumphs, and of advances in surgical technique, I would rather try to throw the searchlight of inquiry in the other direction, and indicate some of the ways in which these very surgical triumphs may themselves throw light upon physiological and pathological problems, and in this way enable surgery in some slight degree to repay something of the debt she owes to these two foundations of her existence.

Thus, to come closely to the matter of my remarks to-day: Consider for a moment the very frequent, nay, the daily establishment of intestinal fistula for surgical purposes.

The operations of colotomy, cholecystotomy, nephrotomy, cystotomy, with the resulting fistulous opening into the bowel, gall-bladder, kidney, and urinary bladder, should enable us, if rightly studied, to observe something of what goes on in the hollow viscera, the biliary canals, and the urinary tract, when the fecal stream or the biliary or urinary flow is wholly or partially diverted from its normal course.

We will consider the fistulous opening in the bowel, established by the operation of colotomy, first. I have in several of these cases tried to ascertain what occurs in the bowel below the colotomy opening by means of the introduction of some insoluble, innocuous pigment, such as hollow suppositories containing a few grains of sterilized indigo or carmine.

From these cases we learn:

First, that in the large intestine, in cases in which the fecal stream has been diverted by previous colotomy, there is an upward current capable of carrying foreign particles, such as powdered indigo, along the bowel, and taking about twenty-four hours to pass from the anus through the sigmoid flexure to the colotomy opening. The shortest time recorded has been twelve hours.

Secondly, that this current is not arrested by the presence of a stricture in the rectum, provided that there is, of course, some patency of channel left.

Thirdly, that it is not essential for this upward current that the fecal current should be wholly diverted or absent, or that the bowel should be prevented from undergoing brisk downward peristalsis, the effect of an aperient.

Fourthly, that this ascending current takes about three days to pass from the anus along the whole length of the large intestine to the cecum.

In offering any explanation as to the means by which this upward carriage of pigment particles is brought about, we must remember that

(1) In the case of the indigo, at any rate, the particles are insoluble in the intestinal juices. Indigo, administered by the mouth, is recovered, unchanged, as far as microscopic appearance goes, from the feces, so that the material is conveyed in particulate masses, probably by a mucous stream, and not by the agency of phagocytes or wandering cells.

*Abstract of the Address in Surgery delivered at the seventy-third annual meeting of the British Medical Association. From advance proofs by courtesy of the editor of the *British Medical Journal*.

(2) The current is absent in the dead bowel, and it not due to capillary flow in a closed tube. If, for instance, indigo is inserted into the lower end of a portion of sheep's colon, removed after death, no ascent of the powder occurs in the tube.

(3) Even in healthy animals, in the absence of any fistulous opening there is some upward flow, though slight, along the bowel. Indigo, inserted into the rectum of a guinea-pig, may be found forty-eight hours later in the feces higher up in the colon.

(4) The current is quickened by any influence, such as the administration of an aperient, which acts by increasing peristalsis, or, very possibly, by increasing the secretion of mucus.

In fact, a consideration of the facts strongly suggests the explanation that the particles of indigo, etc., are carried up the bowel by a mucous current, and that, while there is a central downward current of solid or semisolid feces, caused by peristaltic contraction, there is going on at the same time, intermittently, or possibly alternating with the downward peristalsis, an upward peripheral mucous stream, covering and hugging the intestinal mucous membrane, and capable of conveying minute particles only along with it.

Some sort of upward intestinal current has been suspected in the large bowel, and hypothetically spoken of as due to reversal of the peristaltic wave. This is an unlikely explanation from the facts mentioned above—that it is present while the downward peristalsis is going on at its normal rate, and also when the bowel is quite empty of any feces at all.

I venture to think that these facts have a not unimportant bearing on the physiology of the large intestine. By means of such an upward stream the nutritious fluids and particles, which are being absorbed out of, or squeezed out of, the gradually solidifying and hardening feces, as they traverse the colon, are carried gently upwards into the emptying upper reaches of the bowel and are presented to the free mucous membrane for readier absorption. They, too, have a direct bearing on therapeutics and on the administration of enemata, both nutritive and purgative.

We now pass to the consideration of the female generative canal. Here surgical operations on the Fallopian tubes have afforded opportunities for careful observation.

In a considerable number of cases during the last two years, in which it appeared likely that operation would become necessary on the appendages, after the preliminary douche a little colored pigment—in most cases purified and sterilized indigo, in a few carmine—has been either placed upon, or inserted just within, the os uteri at varying periods up to twenty hours before operation. Careful microscopical examination of the contents of the Fallopian tubes in these cases has nearly always shown the presence of indigo or carmine particles, while in several cases the pigment has been found on the peritoneal surfaces of the broad ligament, mesosalpinx, and the fimbriæ of the Fallopian tubes. This shows that the particles are carried from the os uteri below, right through the uterus and the Fallopian tubes, to the peritoneal sac around the ovary above.

In the case of these pigment particles, automobility (such as the spermatozoa possess) is of course out of the question, and we must fall back on ciliary action, or an ascending mucous stream along the contiguous walls of the mucous canal.

Thus in these twenty-two cases, in which careful examination was made of the contents of the Fallopian tubes and peritoneum for the presence of indigo introduced into the os uteri at periods up to within twenty hours before operation, there were only four in which the pigment was found.

Of these four cases, one was a case of double hydrosalpinx, in which any connection with the uterine cavity was difficult or obliterated. In one the indigo had been inserted only sixteen hours before operation. In two cases the indigo was inserted on the first day of the establishment of the menstrual flow, and probably failed to enter the uterus.

On the other hand, positive results were obtained in three cases of double pyosalpinx. In one case of uterine fibroid and in two cases of tubal pregnancy, in which rupture or tubal abortion had occurred. Indigo was also found in two cases of chronic appendage disease, in which the indigo was inserted on the last day of the menstrual period, and in two cases of hysterectomy, which are of special interest. In one the patient was seventy, and therefore the uterus was senile. In the other the uterus was removed some months after the artificial menopause produced by oöphorectomy twelve months before. These two cases clearly show that this upward mucous stream is not dependent on the functional activity of the uterus, since it occurs in the senile and postclimacteric organ, as well as in the actively functional state. In two cases of large ovarian cysts pigment granules were found on the peritoneum, and in the contents of the tube dilated and stretched over the cyst wall. In a case of suppurating ovarian cyst with pyosalpinx indigo was found in the pus in the tube. It was also found in three case of chronic inflammatory disease of the appendages, probably gonorrheal in origin. In one case of large pyosalpinx the ovarian abscess on one side, and hemosalpinx on the other, operation became necessary while the temperature was 104°, and twenty-eight hours before the operation pus began to escape from the uterus. Indigo was found in the bloody contents of the left tube, but not in the pus of the right tube, or in that of the ovarian abscess. No doubt the particles were washed away from the uterine opening of the right tube by the flow of matter from the opening.

I desire also to draw attention to the presence of the indigo within the pus cells in one of the two cases of pyosalpinx. The granules were actually ingested by the cells, and lay scattered as blue pigment grains in their interior. In fact, we had succeeded in feeding the pus cells with indigo, and had produced an intravitam staining.

Two explanations are possible: Either the material had entered the blood or lymph stream, and had been ingested by leucocytes or phagocytes, which had then migrated into the abscess, or the pus cells had ingested the granules *in situ* in the abscess after the pigment had been carried thither up the Fallopian tube. This will, I believe, prove to be the true explanation, and also carries with it the interesting fact that pus cells, as such, after their entry into an abscess are capable of ingesting foreign particles into their interior.

In the other three cases of double pyosalpinx examined, indigo was found in the pus in the tubes, but not in the cells. Now, in these cases there was no manifest discharge of matter from the uterus, though the presence of indigo in the tubes proves that the communication between the tubes and the uterus was still patent. In fact, I believe that this is the case in most, if not all, cases of pyosalpinx. Blocking, temporary and intermittent, no doubt occurs of the lumen of the tube on the uterine side, but bearing in mind how difficult it is, even by operation, to obliterate the channel by any means, short of excision, I think it very probable that some communication exists in most of these cases of secondary in-

fection of tubes with purulent contents, and that an occasional slight escape of pus occurs, with corresponding relief of intratubal tension.

In fact, the whole subject of tubal regurgitation of uterine contents is very interesting. We know from the artificial production of hydrometra and hydrosalpinx in animals, under aseptic conditions, that regurgitation of the hydrometric fluid from the distended uterus is much prevented by the sudden deviation of the direction which the tube takes in passing through the uterine muscular wall. At the same time, no opposition is encountered by the mobile spermatozoa in their upward passage. And we also now know, from the observations I have just described, that foreign particles of a suitable size, if introduced into the vagina, are habitually carried up the whole length of the genital canal in women. It is not absolutely necessary that the indigo should be inserted into the cervix, for, if deposited in the upper vaginal vault, it is still found occasionally in the tubes at the operation.

The question of the size of the particles is an important one. Particles up to the size of lycopodium grains are carried up, but this seems to be about the limit, as I have found lycopodium (a very few grains) in one case only.

This same upward current exists also in animals, for I have repeatedly found indigo particles in the Fallopian tubes of rabbits after insertion of the powder in the vagina.

I wish also to record an observation at this point on the question of mucous currents in the oviduct of birds. After dusting indigo on the cloacal opening, or after insertion of the powder within the cloaca of fowls, the pigment was found, not only upon, but also sparingly incorporated in, the egg-shell, and I have seen it in the Vitelline membrane, thus showing that it had passed up the oviduct. Further observations are necessary to ascertain whether this occurs only at certain periods or throughout the egg-laying period.

I feel sure, however, from repeated observations during intra-abdominal inspection of the fimbriated ends of the Fallopian tubes during the menstrual period, that regurgitation of menstrual blood and mucus occasionally occurs from the abdominal ostium of the tubes; moreover, blood is sometimes found free in the pelvic cavity without symptoms, and apart from any question of tubal pregnancy. In fact, I have no doubt that in many cases of dysmenorrhea in young women, the pain is really tubal in origin, and is due to peristalsis of the tube in its effort to overcome this regurgitant wave. The pain, in fact, is due to tubal, not uterine, colic.

Let us for a moment consider one other important fact, depending on the establishment of the presence of this upward, uterotubal, mucous current. Those who are brought in contact with uterine cases know that gonorrheal and puerperal poisons, although the most important, do not exhaust all the sources of tubal and peritoneal infection. The mere exposure of the upper vaginal tract to dirt, to lotions and ointments, to any substance surgically unclean, by whatever means introduced, has in many cases originated the salpingitis and chronic endometritis, and I am not without hope that this picture of constant upward mucous current which I have described may produce a greater sense of responsibility in surgeons and tend, perhaps, to check some of the indiscriminate curetting operations which are so fashionable and which (while the only treatment in some cases) in others only aggravate the troubles they are supposed to cure.

Fortunately the door, though open, is guarded by the watchful peritoneum. Foreign particles and fluids introduced, as it were, guttatim, by the tiny canal of the tube, if not too virulent, are at once incarcerated and rendered innocuous. But it should surely make us all most careful to know that any powdered substance we introduce into the os uteri will probably be found within twenty hours, inside the peritoneal cavity.

I shall say a few words later about the means whereby this current is brought about; meanwhile, we pass to the consideration of the upper intestinal tract and the mucous ducts of the glands opening into it.

The gall-bladder is the viscus, which, owing to its frequent exploration and drainage for surgical purposes, is specially adapted for investigation on these lines.

I have examined the bile in several cases of gall-bladder fistula following the removal of gallstones, systematically and daily, for varying periods, indigo being administered by the mouth in cachets containing about 5 gr. during the same period. The bile collected from the fistula is allowed to deposit a sediment, which is examined microscopically, and, in some cases, centrifugalized.

The indigo thus administered by the mouth makes its appearance in the feces about forty-eight hours later, and colors them a dirty or slaty-blue color, which, on microscopical examination, is found to be due to indigo grains in masses. This shows that most of the indigo passes, unchanged, by gastric, pancreatic, or intestinal digestion, through the alimentary canal.

The positive results in several cases examined suggest the fact that a reflux mucous stream becomes established from the duodenal papilla, along the bile ducts to the gall-bladder, in cases in which a fistulous opening has been made into the gall-bladder, and by means of this current the indigo particles are conveyed.

It will no doubt be urged that the indigo was absorbed in the ordinary way, by blood or lymph stream, from the gastric or intestinal mucous membrane, and was only detected in the bile after excretion by the liver. There are, however, many facts which oppose this explanation.

We have seen that indigo passes, for the most part unchanged, through the alimentary canal, and is not absorbed from the stomach or intestine. It is, of course, known that soluble indigo, in the form of sulphindigotate of soda, and other soluble dyes, such as carmine solutions, administered by the mouth, do color the bile.

I find on examination that indigo, itself a very insoluble substance, is slightly soluble in bile, and can be deposited from such solution on evaporation as minute crystaline needles, and never, as far as my own observation goes, in the shape of large or amorphous particles. Now, the indigo obtained from the fistula in these cases was in the form of fair-sized, irregular masses, sometimes bright blue granules, never crystals. Moreover, it is a suggestive fact that they are found chiefly in the mucus lining the gall-bladder, rather than in the rapidly flowing bile.

Further, in two cases indigo was absent from the contents of the gall-bladder and bile-duct at the time of the operation, although the patient had been taking it previously, while it was found in the bile and mucus regurgitating from the fistula when this was fully established some days later.

In order to throw additional light on this point, I fed a guinea-pig for some days with indigo, and then, after killing the animal, examined the contents of the gall-bladder. No indigo was found in the bile contained in the gall-bladder, nor did any crys-

tallize out on evaporating this to dryness. A scraping was then taken of the mucous membrane lining the gall-bladder, and numerous bright blue indigo granules were found. The bladder itself was then opened out on a slide and cleared, but no indigo was found in the peritoneal or muscular coats. This observation is also important, as in this animal the bile and gall-bladder currents were normal, and unaffected by fistula.

On these and other grounds I have no doubt that the indigo found in the bile in these cases is actually conveyed along the mucous channel of the bile and cystic ducts from the duodenum, and not by way of the blood or lymph stream. No doubt, it is only sparingly present, and considerable examination of quantities of bile and mucus is necessary to find it. But we must remember that the opening of the biliary papilla in the duodenum is only a lateral one—an open window, as it were, past which, and not directly into which, the hurrying duodenal stream of semi-digested food is passing, and it is only such few particles of indigo as adhere and cling round the opening of the duct that will be carried by the mucous current along the duct to the gall-bladder.

It will be suggested that if indigo particles find their way thus, why not particles of food? And, indeed, I think it very probable that such small particles do pass in this manner, from the bowel under the altered conditions of the bile circulation, in fistula of the gall-bladder. I have myself found, in the fistulous bile, along with blood cells, bile pigment, epithelial cells, pus, and other substances—particles which look, under the microscope, suspiciously like cellulose and vegetable fiber.

We must remember that, owing to the surgical operation and the establishment of the gall-bladder fistula, the normal action of this viscus has been suspended, there is no longer any outflowing stream of mucus passing from the gall-bladder along the cystic and common bile ducts into the duodenum. In fact, there are many difficulties in accepting the conventional, bile-reservoir, function of the gall-bladder. And in view of the demonstrated importance of a continuous mucous stream, along the bile and other mucous ducts, in the direction of their flow, I am strongly inclined to think that one important, if not the chief, function of the gall-bladder, is to supply this lubricating stream.

The question of the origin of gallstones also intrudes itself on our notice. Does the demonstrated passage of inorganic particles along the bile ducts from the bowel, under the abnormal conditions of gall-bladder fistula, throw any light on this important question?

I fear at present we are not justified in making any definite statement on this point. Given, however, a temporary cessation of normal bile flow along the ducts, or of a normal mucous flow from the gall-bladder—a condition, in fact, produced pathologically, somewhat resembling the condition present in gall-bladder fistula, produced by surgical operation—we may, I think, say this much: That it is probable that not only may the upward passage of even non-motile infective organisms be possible, but that minute foreign particles may, under these conditions, find their way into the gall-bladder and serve as nuclei for the deposition of biliary concretions.

We know from Naunyn's valuable work on cholelithiasis that pathological changes in the epithelium lining the biliary passages, are more important factors in the causation of gallstones than any alteration of the chemical composition of the bile. Naunyn also showed the influence of stagnation of bile in this matter, and the important rôle played by pyogenic organisms derived from the intestine, especially bacillus coli, in causing the cholangitis, and catarrh of the mucous membrane of the ducts.

We know from the observations I have described that the temporary diversion, or reversal of the direction of the bile current bought about by gall-bladder fistula favors the entrance of minute particles from the duodenum into the bile ducts. Does it not, therefore, appear likely that the temporary stagnation of bile flow, probably associated with cholelithiasis, and present in certain pathological conditions of the liver and duodenum, may really operate by bringing about a like entrance of microorganisms along the common duct, with, possibly, minute foreign particles also, which may serve as condensation nuclei. Is it not probable that many cases of so-called catarrhal jaundice are thus explained?

We now pass to the consideration of the urinary tract, from the kidney to the bladder, and from the bladder to the surface, by way of the male and female urethra.

We will consider the ureters first. Reverse infection of the pelvis of the kidney so frequently occurs from interference with bladder function by septic instrumentation, that the ureter is universally regarded as the usual channel of infection, and not the blood-stream. When we come, however, to consider the manner of this ureteral infection, the successive steps are not so clearly known.

In extreme cases of marked obstruction to the outflow of urine from the bladder, in which backward pressure of urine leads to dilatation of the ureters, and in which the interior of the bladder has become infected, by instrumentation or otherwise, it is, of course, quite possible that the open waterway, by arrest or reversal of current, may explain the upward carriage of infective organisms. At present I have not had an opportunity of testing the transference of indigo to the pelvis of the kidney in these cases. The more important point, however, was, if possible, to determine whether, supposing that from any cause (such as the establishment of a renal fistula) the normal downward current of secretion from the kidney to have been arrested—whether under these circumstances and regurgitation of mucous stream occurs in the normal, or at all events undilated and competent, ureter.

The following case of lumbar nephrectomy for cystic destruction of the kidney by calculus impacted in the lower end of the ureter has an important bearing on this point: The calculus was detected by a probe in the ureter at the time of the nephrectomy, but the condition of the patient was such that it was thought wiser to bring the open end of the ureter to the skin surface in the loin, and remove the calculus at a later date through a vaginal incision. This was done one week later, and a good recovery ensued. After the operation of nephrectomy the bladder was irrigated daily, and two drachms of an iodoform emulsion, containig sterilized indigo, allowed to remain in the bladder. The fistulous opening of the ureter on the loin was lightly plugged with a little white sterile gauze. This and the mucopus from the ureter were examined daily, and on three occasions numerous indigo particles were found, showing that here, at all events, a reverse mucous current had passed up the ureter in the absence of any urine.

The position then at present is probably this: Given an arrest, from any cause, of the normal downward current of urine along the ureter, it is possible that a backward mucous current may occur, carrying with it any infective organisms or foreign particles, such as pus, or blood cells, or débris, which may be present in the bladder.

What we do not at present know is whether this regurgitation occurs in those cases of kidney infection in which there is no direct evidence of arrested secretion. We are not at liberty to assume, however, that even in such cases temporary arrest does not occur. It is, indeed, known that the flow of urine from the ureteral orifices is intermittent under normal circumstances; it is possible that this intermittency may be increased to the point of temporary arrest under pathological conditions.

We still have to consider the question of the entrance of infection into the bladder from outside; the conditions, in fact, of the mucous currents in the urethra.

I will first consider the male urethra. The conveyance of infection from the exterior, in the absence of any outside interference, with a normal flow of urine along a healthy urethra is, of course, practically unknown. But, as in the case of the gall-bladder, the frequent performance of suprapubic cystotomy for surgical purposes, in the urinary bladder, affords opportunities of investigating what goes on in the urethral mucous canal.

I have investigated two cases of suprapubic cystotomy in which the bladder was drained by Sprengel's pump after prostatectomy. In both cases indigo placed within the urethra appeared in small amount in the bladder. Now, since all source of accidental contamination from outside was avoided by a dressing over the suprapubic opening, the indigo can only have gained access to the interior of the bladder by traversing the urethral canal. In both these cases no instrument had been passed, and the urethra was uninjured, at any rate, up to the triangular ligament and prostatic portion. All passage of urine had been arrested for some days along the mucous canal.

I have also tried inserting indigo within the urethra alongside of a cathether retained in the urethra and bladder, in cases where it has been necessary for surgical reasons for some days to drain the bladder through a tied-in catheter. In several of these cases I have recovered the indigo from the urine flowing from the catheter, showing that the material has passed centripitally along the urethra to the bladder. I do not feel, however, that much stress can be laid on this, as there is always more or less to and fro, or inward or outward, movement of any instrument tied in the bladder; it tends to be expelled, and is passed back again and resecured, as the movements of the patient alter its position, and it is thus quite possible that, by friction of the instrument against the wall of the urethra, any material might be mechanically conveyed, in successive waves, along the urethra to the bladder.

This objection does not, of course, apply to the previous cases in which no instrument was used; but, at any rate, the experience of the latter case shows how easy it is for infection to be conveyed from a dirty meatus alongside a retained instrument into the bladder; for if inorganic particles can float, as it were, in the mucous stream which is set up between the instrument and the urethral wall, and are carried thus backwards into the bladder, infective organisms can do the same. It is not necessary to assume that they must be conveyed on the point of, or by a dirty instrument; they may reach the bladder by way of the urethra from the surface at the meatus, after the introduction of the instrument.

In fact, surgeons know well that even though the urine be received by a tube direct from the cathether into some antiseptic fluid without contact with the air, yet it is practically impossible to keep the bladder aseptic for any length of time in cases in which an instrument traversing the urethra is tied in the bladder, and I think the above observations throw some light on the manner in which, and the route by which, this infection is brought about. At any rate, they point to the extreme importance of guarding the external orifices, and probably careful disinfection of the external meatus and the application of efficient antiseptic filtering dressings at this spot would have a good influence in preventing bladder infection in the manner above described, especially in those cases (and they should be very few) in which it is necessary to tie an instrument in the bladder.

One word as regards the short female urethra. In one case of vesicovaginal fistula, with a very considerable opening, in which it was necessary to perform suprapubic cystotomy, and operate from within the bladder, the opportunity afforded by subsequent suprapubic drainage was utilized to trace the urethral mucous stream in the female urethra. A little indigo was inserted just within the meatus, and a small filtering plug of sterile gauze inserted in the suprapubic tube through which the urine was draining. Indigo granules were found in the mucus coating this plug when removed six hours later.

We have thus traced the reflux passage of inorganic particles of a recognized substance, like indigo, from the surface, along the urethra to the bladder, and from the bladder to the upper end of the ureter. In all cases the important associated condition has been that the normal flow of urine has been diverted. We still require observations on cases of pyelitis, made at the time of operation, when the pelvis of the kidney is first explored, and in which indigo has previously been inserted into the bladder. Observations on animals will probably be necessary to investigate this point, under conditions in which no previous diversion of the urinary flow has been brought about by surgical operation or disease.

The mode of infection of the epididymis by the tubercle bacillus, or by the gonococcus, or pyogenic organisms requires further examination.

I have not yet been able to test the mucous current in the vas deferens, but I think it likely that sterilized indigo inserted into the prostatic urethra in suitable cases will be recovered from tuberculous and other abscesses in the epididymis or the vesiculæ seminales. If this should occur, then the mucous canal of the vas deferens, and not the blood stream, will probably be the route taken.

With regard to the respiratory tract, and the mucous canals in connection with it, the accessory nasal cavities, the Eustachian tubes, and the bronchi, any observations on this part of the body are all, of course, open to the obvious objection that foreign particles may be, and no doubt are, carried by the air currents and distributed over the mucous surface.

I should, however, like to mention one case of chronic otitis media, with tympanic perforation, in which sterilized indigo was insufflated for four days into the retropharyngeal cavity. The mucopus flowing from the external meatus was collected on both sides, and on the fourth day showed abundant indigo granules.

Of course, it will be objected that, owing to some effort of sneezing, or blowing of the nose, the material was transported up the canals by a blast of air. The patient was instructed to avoid all such sudden expiratory efforts, and I am inclined to think that the presence of the indigo in the internal ear is not due to this cause.

Supposing, however, that such is the case, it is surely a matter of considerable importance that in, at any rate, cases of perforated drums, not only air

currents should pass habitually from pharynx to middle ear, but that foreign particles should also find their way up the Eustachian tubes in the absence, of course, of all instrumentation. The bearing of this on the question of conveyance of infection from pharynx to middle ear is obvious, though in the case of tympanic perforation the important condition of diverted flow is present.

We now pass to the consideration of the glands with ducts opening on to the surface of the body, and the possible conveyance of pigment particles along the ducts, from the skin to the alveoli of the glands.

The mammary gland, with its numerous ducts opening on the nipple, is the largest and most important of these glands. In a case of duct cancer of the breast, for six days before the removal of the breast sterilized indigo was rubbed on the nipple twice daily, and a simple dressing of wool worn. Great care must of course be taken to avoid contamination of the exposed breast tissues at the time of the operation, but this, after all, is an object lesson in surgical technique, and the same precautions in the way of repeated washing and sterilization of the skin, which are taken to prevent contamination by skin organisms will apply to the indigo also. In order to insure absence of contamination, I have either coated the nipple and surrounding skin to be excised with a layer of gauze and collodion, or, having turned the flap of skin to be excised upwards and inwards all around the nipple, I have tied this by a purse-string suture, thus leaving only the raw surfaces exposed.

The whole breast, after removal, is laid on a slab, with the deep surface uppermost, and incisions are made into the breast tissue in the neighborhood of the ducts, and into the portion affected by the cancer. Scrapings were taken from these incisions, and indigo granules were found sparingly, but from several parts of the breast. Other cases of mammary cancer have yielded the same result. I have also examined unstained sections of breast tissues obtained in the same way in two cases of cystic disease associated with chronic mastitis, in which indigo had previously been applied to the nipple, and detected it in the breast.

In a case of chronic mastitis, with a scirrhous nodule in one part of the breast, in which indigo was applied for four days before operation, the pigment was found in the portion of the mammary tissue containing the ducts, just beneath the nipple, but not in the solid portion invaded by growth. Now, the importance of this fact, of the conveyance of pigment particles from the skin to the deeper parts of the mammary gland along the lacteal ducts, lies in its application to the question of the transference of infective organisms by the same route.

Here again it is a question of conveyance by blood, or lymph stream, as against transference by mucous currents along the ducts, and it seems to me that the demonstration of the passage of inorganic pigment particles by this latter route strongly confirms the suspicion that it is by these duct channels that pyogenic, and probably tuberculous, organisms gain access to the mammary gland.

I feel some hesitation, in the present unsettled state of the cancer problem, in mentioning cancer in this connection. All I will permit myself to say is this: That if, in the course of future research, the exciting cause of cancer shall be proved to be parasitic, the above observations may stimulate inquiry into the nipple route as a possible channel of infection in cancer of the breast.

**Conclusions.**—We have now passed in review the conditions present in the more important mucous canals, and gland ducts opening in the interior of the body, and in one case in the ducts of a gland opening on the skin surface, and a few general observations bearing on the facts so observed may not be out of place.

I think from the observations I have described we may consider it proved that by some means or other, and under certain conditions, particles of an insoluble substance, such as indigo, inserted into the orifices of a mucous canal, or duct, are converted along the mucous channel in a reverse direction to that taken by the contents of the tube, or by the secretion or excretion of the glands along such ducts. The conditions which seem to favor this passage are:

First, some interference with the normal flow of the contents of the mucous tube or duct; some arrest or diversion of secretion, such as is produced by a fistulous opening, though it is by no means necessary that this should be complete. By what agency is this transference of foreign particles brought about?

*Ciliary Action.*—Though present in the upper generative tract, cilia are absent in the lower genital tract, in the intestinal canal, in the biliary ducts, in the urinary tract, and in the ducts or glands opening on the skin.

*Muscular Contraction.*—No doubt irregular or reversed peristaltic contractions in the bowel, if present, would bring about the result. It is, however, suggestive that the ascent of the indigo up the colon is not prevented, but rather accelerated, by the increased downward peristalsis produced by purgatives. Reverse muscular contractions are as yet, moreover, unknown, or, rather, undemonstrated in the bile ducts, urethra and urinary tubes, Fallopian tubes, or in the ducts of glands.

The phenomenon is not due to physical agency alone, such as capillary action. It is absent in the non-living tube. The transference of particles in empty tubes and ducts is one, and there are other reasons, before explained, for regarding the mucus which coats the walls of the tube, or duct, as the vehicle in which the particles are carried. Further observations are necessary to ascertain whether a reverse current—a sort of mucous backwater—is present in all mucous channels, or whether it only exists where the normal outgoing current of secretion or excretion is interfered with. Such a back current is probably present to a certain extent normally, though much increased by an agency, such as a fistula, which starts a flow of mucus from the other end of the canal.

The essential conditions, then, seem to be a living tube, whose walls are partially, if not wholly, in apposition, and lined by a mucous secretion; while the reversal of this mucous current is favored by any condition (such as a fistula) which leads to arrest or diversion of the ordinary secretion of the viscus or gland.

The bearing of these remarks on the larger question of infection will be at once apparent.

I am inclined to think that in some cases more attention should be paid to mucous channels as routes of invasion, rather than to the lymph or blood stream. Thus I have spoken of the large share which such a mucous, as opposed to a blood infection, plays in the diseases of the female generative tract. The rapid ascent of the urethra by the non-motile gonococcus, and the colonization of deeper portions of the tube, apart from direct extension of growth and in the absence of instrumentation or injection are thus explained. The ascending infections of the kidney by way of the ureter can also be investigated from this point of view.

Our knowledge of the causes which produce biliary and urinary calculi is still very incomplete. The facts which point to the importance of diseased conditions of the mucous linings of the excretory tubes, in favoring the deposition of concretions, are of especial importance from this point of view. And, bearing in mind the proved transference of particles under certain conditions, from the duodenum to gall-bladder, and from urethra to ureter, I hope that further light may thus be thrown on these calculous diseases.

In fact, the burden of my remarks points to the necessity for the active recognition of the importance of all communications between the efferent canals of the body and the external world, and thus accentuates the value of personal hygiene and true cleanliness.

## DYNAMICS OF DREAMS.

By AXEL EMIL GIBSON, M.D.,

LOS ANGELES, CAL.

When the white ray of light is permitted to fall through a prism, it becomes sundered into seven specific rays of colors, each one exhibiting distinct characteristics in relation and in response to the nature of its environment. In a corresponding way, the single cell, constituting a prism through which a passage is found for the stream of universal life, breaks the latter into the numberless structures which are springing up in the course of natural evolution.

The only stable point or synthetizing factor in this ever-fluctuating sea of evolution, where forms appear and disappear, increase, culminate, and decrease in the restless metamorphosis of growth, is the informing center of intelligence—the personal Ego, or Soul. Indivisible and indestructible, this center of individuality persists and keeps intact in the midst of the wrecks and break-downs of forms and structures on the battlefield of evolution. It is in this egoity—this power of conscious identity—that we find the helmsman who holds the tossed and battered vessel of life to its true compass. The confused surge of cellular and functional activities with their storms of sensory reports never for a moment succeed in silencing the one clear, penetrating note of individuality.

Now if the cell be allowed to represent a prism of *life*, the individuality may stand for a prism of *consciousness*. And as it is in the response to the evolutionary life-impulse of the various cell-structures and organisms that the latter receive their several forms and characteristics, so it is in the reactions of the Ego to the pressure of consciousness that we find the source of the various shades and degrees of intelligence expressed in waking or dreaming life.

With sleep is understood either partial or general suspense of physiological activities in an entity for recreative purposes. But sleep refers only to outward existence—to the relations of the life to its objective or physiological pole; while in its subjective, ideative, and dynamic aspects, life, even during sleep, remains fully awake, active and demonstrative; and it is in this latter condition that life, unhampered by the turmoil of objective existence, introduces the dramatic representations which we know as dreams.

Brought by sleep into relationship with this purely subjective phase of life, the Ego plunges into dreamland. This gives to dreams a meaning at once as universal and as particular, as natural and as philosophical as its antipode—waking. They constitute the two ends of a balance; one ascends when the other decends—the one forming the complement of the other. Nor is dream limited to the kingdom of man. That animals dream can easily be ascertained by watching dogs during sleep, when they often bark and strike attitudes of excitement and animation, indicating engagement in some chase. In fact it can safely be said that whatever is susceptible of sleeping, also is susceptible of dreaming. And as plants sleep, so they also are found to have relapses into a state of sub-consciousness corresponding to dream. Through exhaustive experiments it has been brought beyond the realm of doubt that the *Mimosa* and its sub-orders, under hypnotic treatment lose their sensitiveness, and glide into a state of life, different from the normal, which must mean something analogous to dream. And we may extend this borderline of dream still farther, until it embraces every form or unit of life. For if groups or combinations of cells (organisms) sleep and dream, so the individual cells themselves must sleep and dream, as the whole can possess no characteristics not contained in the parts of which it is made up.

It is this power of the cell to enter into dream life that lies back of what has been termed prognostic dreams. Harvey, of the vascular circulation fame, records a dream in which a bumble-bee stung him in his left thigh, on a place where a couple of days later appeared an ugly ulcer, and Malesherbe, the renowned French author, found himself in a dream attacked by a rowdy who stabbed him in his left breast with a dagger in an area where the following evening he felt the first attack of a severe lobar pneumonia. The archives of medical reports are heavy with cases of similar characters, which have either received no explanation at all, or else have been explained away entirely.

But facts are stubborn things to deal with, and while mutable and elusive as ghosts, they nevertheless possess the endurance and indestructibility of elemental forces. A fact is an implacable sphinx confronting the wayfarer with its ominous riddle; and similar to the conditions of old, only one right-of-way is obtainable: the solving of the riddle.

The prognostic dream is the result of cellular experiences along subjective paths of consciousness during sleep, when the stillness of objective life permits the turning of self-consciousness towards inner aspects of existence. Dipolarized to the life-current in its constructive and organizing action, the cells, either as units or as functional structures, become attuned and receptive to impulses of the subjective and unmanifested side of nature. Polarized to this purely subjective aspect of life, the cell-units are brought into reciprocal touch with potency in place of potentiality, with the ideative in place of the manifestive forces of evolution, and charged with their currents. Like every other force, life flows along the lines of least resistance, from the subjective to the objective plane, giving rise to disturbances and friction wherever it meets points of obstruction. And it is these obstructions in the flow of consciousness, appearing in the subjective or dreaming mind as more or less fragmentary issues of intelligence, that are used by the Ego as constructive material in the dramatization and staging of its dreams.

And this may furnish a clew to the prognostic powers of the dreams experienced by Harvey and Malesherbe. For the sting of the bumble-bee and the stab of the dagger in the duel, constitute "*dramatis personæ*" introduced by the Ego, and constructed from disturbances ensuing somewhere along the transition line between subjective and objective life; the line where the psychic or mental *impressions* are passing over into physiological or functional *expressions*. The emergence in dream-

life of the brooding disturbance, prior to its manifestation in the body as a palpable disease, is due to the different media of transmission as represented by the noise of the waking and the quiet of the sleeping consciousness. In the quietude of the senses following upon sleep, when the storm of mental reflexes is subdued, the finer changes of life may be brought into notice. Prophetic dreams may, therefore, not be without a scientific basis.

But it is not necessary that an image, to appear in the mind awake or adream, must be generated in the consciousness of that mind or Ego itself. Through thought transmission, or telepathy, images and ideas may be projected from one mind into another, to start trains of emotions and mental processes capable of exerting the same strength of influence as if integral to the influenced mind itself. It is in accordance with this again and again verified fact that Dr. Charcot, in *La Saltpêtrière*, succeeded in conducting the trains of events in the dreams of his patient-subjects, by silently inducing thought-images into their hypnotized minds. External noises, faintly transmitted by the semi-dormant senses of the sleeper to the retired mind of the Ego, may produce the same effect. Thus Prof. Hansen of Copenhagen, in his interesting reports of individual experiments with his pupils, mentions how in one case the noise of a passing carriage started a long series of dramatic representations in the mind of the dreamer, involving thunderstorms, journeyings, accidents of various kinds, etc. And as memory is the storeroom of events, or, perhaps more correctly stated, the gallery of pictures, to which the key is found in the idea-association started by external or internal incidents in the mind of the dreamer, it follows that the latter will have ample opportunities to find material in his dormant memories for the extending and rounding out of the subjective sketches in his dream-life.

But there are dreams in which the law of causation seems to be defied, and where the effect apparently precedes the cause. Thus in his book, "Traite des Facultés de l'Ame," Dr. Garnier mentions the case of the first Napoleon, who was sitting asleep in his carriage at the time the famous explosion of the infernal machine took place almost immediately under it. The noise of the explosion aroused him from a long dream, in which he was crossing the Tagliamento with his army. Suddenly encountering an unexpected cannonade from a masked battery of the Austrians, he exclaimed: "We are undermined," and awoke. It is evident that the report which aroused the Emperor from his dream was the very report that gave rise and contents to it, and consequently presented a case where the effect must have preceded the cause.

This reversion of causality, however, is merely apparent. For from the arguments already presented in this paper, it has been seen that the self-conscious Ego oscillates between the two poles of subjective and objective existence, receiving its knowledge by consciously reacting upon impulses, which may or may not reach it through the media of sense-functions. For, as in our telegraphic communications, we have a system with wire connections and a system without wire connections, so in the body we possess corresponding systems of communication where the mental or sensuous impressions may or may not be transmitted through the connecting wires of the nerves. And that such wireless or nerveless connections exist in the physical organism is demonstrated in the physiological phenomenon known as *pseudopodium*—an amebic protrusion for locomotive purposes—by which a phagocyte under the stimulus of some trackless impulse may all of a sudden desert his field of action and hasten through intervening tissues and cell-wall divisions to a point where its immediate presence is needed. Thus a phagocyte stationed somewhere, let us say in one of the finger ends, may receive intelligence concerning a bacterial invasion of some distant part of the organism without the involvement of demonstrably known nerve paths.

Now, in the case of Napoleon's dream and other similar cases, the nerve-cells of special sensation being charged simultaneously at what may be termed their sensuous-objective and sensuous-subjective poles, the length of time required for the transmission of the message from the transmitting to the receiving stations must of necessity depend on the media of conduction. The objective sense-impulse with its conduits passing over demonstrable nerve connections requires, according to the measurements of Paul Bert, a time of one minute for every thirty meters of distance. Hence the time for the transmission of an impulse from any anatomical point to the central station—*medulla oblongata*—is appreciable in terms of direct measurement; while the subjective discharges, with their instinctive rise in consciousness, and, proceeding along the "wireless," or rather "fiberless," system of transmission, can be conceived of only as a pure psychic impulse, reaching the sensorium on no known or appreciable medium of conduction, and hence subject to no condition of time or space. The interval ensuing between the time of arrival at the medulla of the two evoked impulses—the objective and subjective, or physiological and psychical—would furnish opportunity for the timeless and unconditioned subconscious Ego to elaborate the involved subject matter into the drama of a dream, and even run through its stage performance before the auditory nerve, along the fiber of special sensation, would have had time to approach the medulla with a note of warning resulting in the awakening of the Ego and the subsequent closing of the dream.

Perhaps no phenomenon of consciousness is more convincing with regard to the fact of a dual system of transmission of sense-impressions than the effects arising from stupefaction through narcotics. An experience often occurring to persons held under chloroform consists in the miraculously short time passed in unconsciousness, which can be explained only by the different standard of time prevailing in the sleeping and waking states of consciousness. The scale of time is changed during the dream, while memory still presents the series of events as related to normal time, and which, upon waking, is held as standard in forming a judgment of the length of time occupied in the process. Now, however, as the nervous system is adjusted to physiological laws in terms of normal time, it follows that any other scale by which the succession of events can be measured operates in independence of the nervous system.

In dreams, ideas are substituted by images. To think of a place or of a person means to enjoy their immediate presence. And the rationale for this seeming incongruity is by no means undiscoverable, though the explanation may be found somewhere else than in the mere statement that the condition is the result of the workings of an unhampered imagination. For imagination itself needs an explanation, as its subtle, yet epochal work in the processes of constructive intelligence is neither understood nor appreciated. Plato has said somewhere that imagination is seeing, and knowledge is memory—statements which on their very face bear the stamp of a profound significance. For if imagination is seeing, then evi-

dently the power of vision involved in this seeing depends for its functioning on some other media than the retina, crystalline lens, and optic thalami. From the fact, brought to light by a closer observation of the movements of the single cell, namely, that function precedes structure, has sprung, by sheer force of logic, the still more important fact, that function as such can exist in independence of structure. Brought under the influences of environments where opportunities for the development of a certain function are at hand, the organism will gradually evolve corresponding structures. Yet structure does not more exhaust the capacity of the indwelling function than a field glass limits the functional capacity of the eye in general vision. So, for instance, in dream, when the sensory structures are all suspended and inert, the corresponding functions are in full operation. For no one will deny that the dreamer in his journeyings and sight-seeing, and in his power to enjoy the charms of music, depends on some other media than those known to us as the five sense-organs. A most conclusive evidence in favor of this view is found in the circumstance that even the blind are able to see in dreams—as witness the experiences recorded by Helen Keller, "Blind Tom," the poet of "Paradise Lost," and others. Nor is this power limited to the kingdom of man. An accidentally blinded seal, brought under the observation of Charles Darwin, was, according to the statement of this great scientist, capable of finding its way from the Isle of Man to Cape Clear on the south coast of Ireland. Hence the conclusion seems to be unavoidable that it is only as far as physical vision is concerned that the optic nerve guides and limits the field of vision. If we are to believe the personal records of Michael Angelo, Milton, Helen Keller, and others, it must even be conceded that the absence of the physical eye, so far from arresting the vision of consciousness, adds to it powers of penetration and exaltation. For any representation of form, position, or expression, be it on the subjective or objective plane, necessarily involves the power of vision. Nor does this view lack scientific basis, as every single cell of the body possesses functional power, adequate for the evolution of any special sense, and thus conferring to every mathematical point of the organism a power of vision. Brought under the stress of necessity, the body may become all eye, or all ear, or, as at present, all touch. In the evolution of life we find environment furnish opportunities, and necessity furnish force, by the cooperation of which, ideal funcaions become externalized into organic structures.

For what is the rationale of this paragraph from Berlin, dated the 8th of June last year, and containing the statement that Dr. Lunden has proved by actual experiment that rays collected from radium enable blind persons to see more or less clearly? What, if not the amazing fact, that by the vibrations of these mysterious rays the optic thalami and basal ganglia by responding to new conditions, may yield new functions—unique and unknown—through which the undying function of vision may find new means of expression? For, while function precedes and transcends structure, it yet depends on, and is conditioned by it, when pressing for sensuous manifestation.

Now, in sleep, the whole optic apparatus is placed under temporary arrest. Dislodged from the channels of physical vision, the function of sight, still intact and seeking for expression, reappers in a new mode of manifestation on the plane of dream. To explain away the power of sight in dream by calling it imagination does not detract anything from its true functional value. For in its last analysis what is imagination but an expression of the same power which manifests in physical vision, though functioning through structures other and subtler than those of the cerebral nuclei and connected optic apparatus? In waking consciousness, while our minds are blinded by the blazing pyrotechnics and flitting apparitions of the senses, the vision of imagination remains dim and uncertain, and may even impart misleading representations to consciousness. For just as there is a difference between mere seeing and observing, so there is a difference between the idle day-dreams of an untrained imagination and the strong, vivid realization of ideal prototypes, as experienced by poets and artists, in whom imagination is developed into a distinct and reliable function of subjective seeing.

Now in dream, when the turmoil and disturbance of the waking consciousness is kept in abeyance, the powers of imagination are set free, turning every individual, to some degree, into an artist and a seer. Manifesting along the lines of least resistance, the power of consciousness, when finding its sensory avenues through physical fatigue rendered unavailable, seeks expression through interior and more subtle structures. For the difference between visions of dream (imagination) and visions of waking (ordinary seeing) consists in the difference of the involved structural media, and as a change of octave in a musical instrument reveals new tonal powers, so the introduction through sleep of a new medium for vision gives to the world-picture a new perspective. Nothing new, however, has been brought out; dream reveals, but does not create. It presents the same seer, the same function, the same world; only the viewpoint is changed, which again results in the appearance of new aspects, with corresponding powers of universal expression.

Waking or dreaming, the connecting link which holds the experiences of self-consciousness together, either as image or event, is found in memory. Individuality, personality, identity of Ego, rationality of perception, and logic of conception have their sole possibility and explanation in memory. The latter holds in the mental world the same influence as cohesion in the molecular world. Every cell-unit is equipped with power of memory. For what is habit but the collective impulse formed by the memories of numberless cells, and aiming at the repetition of once inaugurated vegetative processes. Biologically or psychically considered, memory constitutes the recording film in the phonograph of human consciousness, and every thought, motion, or event impinges on this film its minute and indelible tracings. Hence memory is not an individual process, limited to personal minds, but a universal process, involving every aspect and movement of life and consciousness. Had memory its seat and center in the brain, its power of yielding recollections would be incomprehensible. Nor would the physical structures of the brain be adequate to hold the numberless and ceaselessly increasing records of memory. In his treatise on human memory, Dr. Huber of Heidelberg furnishes some very ingenious calculations with regard to the relation between the volume of the brain-substance and memory. If one-third of a second, Dr. Huber reasons, suffices for the production of an impression, then during the time of 100 years a man's brain must have accommodated for some 9,467,280,000 impressions. Now, however, as one-third of the human life is spent in sleep, a reduction of that amount must be made from the total, leaving the final sum of 3,155,760,000 impressions, which, limited to a course of 50 years, would amount to 1,577,880,000. Now as the brain-substance on an average, weighs about four pounds, from which,

however, must be reduced one pound for blood and vessels, and another pound for external integuments, there remains as the final result of the calculation a sum total of 205,542 traces to be impressed on each single grain of brain-substance!

If we thus fail to locate the seat of memory in the physical brain, we are, by force of circumstances, induced to search for it in the mind itself, the substance of which, ethereal and impalpable, would set no limits to its recording powers. From this mental or psychic storehouse it is not improbable that the dreaming Ego may obtain the material by which to rear its fairy structures. If so, it would further follow that the motives, ideas, emotions, thoughts, and feelings, with which we employ our minds during every moment of time, go to form our character and to influence our life for good or bad, in waking or dreaming. Held as living images in the picture gallery of memory, in the zone of the mind, this mental output forms the Banquo's ghost of our existence, pursuing us with their influence in every walk of life, and if base and selfish will weaken our will, blur our intuition, and unbalance our judgment. And as the processes of memory are identical for waking and dreaming consciousness, it follows that ordinary dreams are children of our mind, and influenced by the character and attitude of the latter. Dreams, be they grotesque or exalted, must, therefore, of necessity have a basis in our mental and moral constitution, though their ruling elements may have been so deeply buried in our nature that our waking consciousness fails to take notice of them.

As the dream presents incidents and conditions unknown to the waking man, it might be said that to some extent all dreams are prophetic. If adjusted in consciousness to the memories of the cells of his body, the dreamer, in the quietude of the sensory exchanges, may become the recipient of truths concerning his physiological conditions.

Such dreams are prognostic, and may, if the dreamer be sufficiently sensitive to the cellular consciousness of his body, also become prophylactic, and set free powers of self-prescription. With such powers is meant a function already present in animals and plants in the form of instinct. It is the power of self-preservation—the force back of natural evolution, which practically determines the survival value of every entity. In the absence of the storms of emotions and passions, which in the human mind continues to drown almost every other expression of consciousness than that of sensation, the nature of the animal is receptive and responsive to the needs of its cell-lives. From this springs the startling power of self-diagnosis and self-prescription, so frequently and incomprehensibly exhibited by the animals, when overtaken by accident or ill health.

For what is this inexplicable power of the animal to select the kind of food conducive to its health, and avoid all others, but a form of self-prescription—a concomitant to self-preservation? The highly artificial existence which prevails at present in human society has not yet succeeded in breaking down every vestige of this instinctive power, once native to every entity of evolution. Thus idosyncrasies, by which the individual, by more or less powerful physiological disorders, is made aware of the injurious effect an indulgence in a certain food, a certain berry, or vegetable, etc., may have upon his system. Some persons are kept away from strawberries and crawfish by what is known as "St. Anthony's fire." Goethe's antipathy to garlic amounted to convulsions, and Napoleon felt attacks of cramp in his intestines at the mere sight of brown cabbage.

On the other hand, we find that the same mystic intelligence, which through involuntary and inexplicable aversions or idiosyncrasies prescribes for the individual what substances to avoid, in a no less distinct way, when conditions demand it, informs the individual of substances necessary for his existence. Hence these numerous instances of travelers famishing in the desert, who see images of oases and springs, banquets with delicious repasts, etc., but powerless to enjoy them, like once Tantalus before the receding viands. The famous traveler and author, Mungo Park, has brought such experiences under scientific scrutiny by furnishing day-book notations during a journey in Africa, when overtaken by a fainting spell, due to hunger and thirst, he dreamed, awake, of the richly-watered valleys and pastures of his home.

Hence hunger itself is a health-prescription by which the human self-consciousness is made aware of certain physiological necessities of the body. Now as impulses or instincts in the generality of cases fail to make their presence known to the mind, owing to the turbulence of thoughts, and storms or emotions sweeping through the sensorium, it requires the inner and outer quietness of sleep to develop a clear image in consciousness of what is needed to restore a broken physiological equilibrium. This development, however, of an idea into an appropriate image —the instinctive impulse turned into analytic self-prescriptions—is a course which nature resorts to only when her ordinary sanative power does not suffice for the removal of a disease, but requires special remedies from the external world. Or, as Schopenhauer expresses the same thought in his work, *Parerga*: "Nature herself kindles a light by which the assistance needed by the organism from without can be sought and obtained."

Thus, if mindful to the impulses of a nature which ever surrounds her entities with means and opportunities for their protection, the individual will be safeguarded against disease and premature death. But to be responsive to nature means to be obedient to her laws, and which again means to live in accordance with our individual sense of duty and conscience regarding the measures and limits for sanitary indulgences. It is in this circumstance we find exhibited the powers of different individuals, to feel, and to interpret nature's healing impulses. Thus it is not in the absence of these impulses that the infrequency of the power of self-prescription is to be explained, but rather in the failure of the individual to exert the purity and open mindedness which forms the condition for all receptivity and growth.

This power of nature to reveal to the mind what is needful for the body was recognized by the sages and savants way back in the days preceding our era. Plato is recorded as having made the observation that when "desire arises, imagination comes in and presents the object." And this not only in sleep and dream, but also in waking. For what are hunger and thirst in the healthy, sane mind, but suggestions from nature, referring to the special things needed for preservation of health? In dream, these suggestions under the formative power of imagination present themselves as images or symbols. In extreme cases, when the life of an individual is threatened by the absence of certain vital necessities, as in the case of shipwrecked, starving sailors, nature, realizing the seriousness of the situation, does not wait for the approach of sleep, but pierces the waking consciousness itself with her life-saving message. Through a vivid imagery she presents in unmistakable forms and colors the means needed for the occasion. The delicious repasts miraged before the inner vision of such unfortunates receive their reason and purpose only when gauged by the

meaningful power of nature extended in behalf of the health and survival-value of her creatures.

This sanative undercurrent of natural evolution proceeds every moment of time in waking, no less than in sleeping life. But, like the light of the stars which appear only during the night when the brighter light of the sun has passed out from the field of vision, so the admonitions and health instincts of nature rise to the level of self-consciousness only after the storms of sensation incident to waking existence have subsided for the calmness and quietude of sleep.
